

High Voltage Input Integrated Switch Step-Down Regulator

Features

- Up to 96% Typical Efficiency
- Input Voltage Range: 4.0V to 30V
- Output Voltage Range: 2.0V to 15V
- 2% Output Voltage Accuracy
- Integrated N-Channel Buck Switch: 460 mΩ
- 600 mA Output Current
- 500 kHz Fixed Frequency
- Adjustable Output Voltage
- Low Device Shutdown Current
- Peak Current Mode Control
- Internal Compensation
- Stable with Ceramic Capacitors
- Internal Soft-Start
- Cycle by Cycle Peak Current Limit
- Under Voltage Lockout (UVLO): 3.5V
- Overtemperature Protection
- Available Package: SOT-23-6

Applications

- PIC[®]/dsPIC Microcontroller Bias Supply
- 24V Industrial Input DC-DC Conversion
- Set-Top Boxes
- DSL Cable Modems
- Automotive
- Wall Cube Regulation
- SLA Battery Powered Devices
- AC-DC Digital Control Power Source
- Power Meters
- D² Package Linear Regulator Replacement
 - See [Figure 5-2](#)
- Consumer
- Medical and Health Care
- Distributed Power Supplies

General Description

The MCP16301 is a highly integrated, high-efficiency, fixed frequency, step-down DC-DC converter in a popular 6-pin SOT-23 package that operates from input voltage sources up to 30V. Integrated features include a high side switch, fixed frequency Peak Current Mode Control, internal compensation, peak current limit and overtemperature protection. Minimal external components are necessary to develop a complete step-down DC-DC converter power supply.

High converter efficiency is achieved by integrating the current limited, low resistance, high-speed N-Channel MOSFET and associated drive circuitry. High switching frequency minimizes the size of external filtering components resulting in a small solution size.

The MCP16301 can supply 600 mA of continuous current while regulating the output voltage from 2.0V to 15V. An integrated, high-performance peak current mode architecture keeps the output voltage tightly regulated, even during input voltage steps and output current transient conditions that are common in power systems.

The EN input is used to turn the device on and off. While turned off, only a few micro amps of current are consumed from the input for power shedding and load distribution applications.

Output voltage is set with an external resistor divider. The MCP16301 is offered in a space saving SOT-23-6 surface mount package.

Package Type

MCP16301

Typical Applications

1.0 ELECTRICAL CHARACTERISTICS

Absolute Maximum Ratings †

$V_{IN, SW}$	-0.5V to 40V
BOOST – GND	-0.5V to 46V
BOOST – SW Voltage.....	-0.5V to 6.0V
V_{FB} Voltage	-0.5V to 6.0V
EN Voltage	-0.5V to ($V_{IN} + 0.3V$)
Output Short Circuit Current	Continuous
Power Dissipation	Internally Limited
Storage Temperature	-65°C to +150°C
Ambient Temperature with Power Applied	-40°C to +85°C
Operating Junction Temperature.....	-40°C to +125°C
ESD Protection On All Pins:	
HBM.....	3 kV
MM.....	200 V

† **Notice:** Stresses above those listed under “Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operational sections of this specification is not intended. Exposure to maximum rating conditions for extended periods may affect device reliability.

DC CHARACTERISTICS

3.0 PIN DESCRIPTIONS

The descriptions of the pins are listed in [Table 3-1](#).

TABLE 3-1: PIN FUNCTION TABLE

MCP16301 SOT-23	Symbol	Description
1	BOOST	Boost voltage that drives the internal NMOS control switch. A bootstrap capacitor is connected between the BOOST and SW pins.
2	GND	Ground Pin
3	V _{FB}	Output voltage feedback pin. Connect V _{FB} to an external resistor divider to set the output voltage.
4	EN	Enable pin. Logic high enables the operation. Do not allow this pin to float.
5	V _{IN}	Input supply voltage pin for power and internal biasing.
6	SW	Output switch node, connects to the inductor, freewheeling diode and the bootstrap capacitor.

3.1 Boost Pin (BOOST)

The high side of the floating supply used to turn the integrated N-Channel MOSFET on and off is connected to the boost pin.

3.2 Ground Pin (GND)

The ground or return pin is used for circuit ground connection. The length of the trace from the input cap return, output cap return and GND pin should be made as short as possible to minimize the noise on the GND pin.

3.3 Feedback Voltage Pin (V_{FB})

The V_{FB} pin is used to provide output voltage regulation by using a resistor divider. The V_{FB} voltage will be 0.800V typical with the output voltage in regulation.

3.4 Enable Pin (EN)

The EN pin is a logic-level input used to enable or disable the device switching, and lower the quiescent current while disabled. A logic high (> 1.4V) will enable the regulator output. A logic low (<0.4V) will ensure that the regulator is disabled.

3.5 Power Supply Input Voltage Pin (V_{IN})

Connect the input voltage source to V_{IN}. The input source should be decoupled to GND with a 4.7 μF - 20 μF capacitor, depending on the impedance of the source and output current. The input capacitor provides AC current for the power switch and a stable voltage source for the internal device power. This capacitor should be connected as close as possible to the V_{IN} and GND pins. For lighter load applications, a 1 μF X7R or X5R ceramic capacitor can be used.

3.6 Switch Pin (SW)

The switch node pin is connected internally to the N-channel switch, and externally to the SW node consisting of the inductor and Schottky diode. The SW node can rise very fast as a result of the internal switch turning on. The external Schottky diode should be connected close to the SW node and GND.

MCP16301

NOTES:

4.0 DETAILED DESCRIPTION

4.1 Device Overview

The MCP16301 is a high input voltage step-down regulator, capable of supplying 600 mA to a regulated output voltage from 2.0V to 15V. Internally, the trimmed 500 kHz oscillator provides a fixed frequency, while the Peak Current Mode Control architecture varies the duty cycle for output voltage regulation. An internal floating driver is used to turn the high side integrated N-Channel MOSFET on and off. The power for this driver is derived from an external boost capacitor whose energy is supplied from a fixed voltage ranging between 3.0V and 5.5V, typically the input or output voltage of the converter. For applications with an output voltage outside of this range, 12V for example, the boost capacitor bias can be derived from the output using a simple Zener diode regulator.

4.1.1 INTERNAL REFERENCE VOLTAGE

$$V_{REF}$$

An integrated precise 0.8V reference combined with an external resistor divider sets the desired converter output voltage. The resistor divider range can vary without affecting the control system gain. High-value resistors consume less current, but are more susceptible to noise.

4.1.2 INTERNAL COMPENSATION

All control system components necessary for stable operation over the entire device operating range are integrated, including the error amplifier and inductor current slope compensation. To add the proper amount of slope compensation, the inductor value changes along with the output voltage (see [Table 5-1](#)).

4.1.3 EXTERNAL COMPONENTS

External components consist of:

- input capacitor
- output filter (Inductor and Capacitor)
- freewheeling diode
- boost capacitor
- boost blocking diode
- resistor divider.

The selection of the external inductor, output capacitor, input capacitor and freewheeling diode is dependent upon the output voltage and the maximum output current.

4.1.4 ENABLE INPUT

Enable input, (EN), is used to enable and disable the device. If disabled, the MCP16301 device consumes a minimal current from the input. Once enabled, the internal soft start controls the output voltage rate of rise, preventing high-inrush current and output voltage overshoot.

4.1.5 SOFT START

The internal reference voltage rate of rise is controlled during startup, minimizing the output voltage overshoot and the inrush current.

4.1.6 UNDER VOLTAGE LOCKOUT

An integrated Under Voltage Lockout (UVLO) prevents the converter from starting until the input voltage is high enough for normal operation. The converter will typically start at 3.5V and operate down to 3.0V. Hysteresis is added to prevent starting and stopping during startup, as a result of loading the input voltage source.

4.1.7 OVERTEMPERATURE PROTECTION

Overtemperature protection limits the silicon die temperature to 150°C by turning the converter off. The normal switching resumes at 120°C.

MCP16301

FIGURE 4-1: MCP16301 Block Diagram.

4.2 Functional Description

4.2.1 STEP-DOWN OR BUCK CONVERTER

The MCP16301 is a non-synchronous, step-down or buck converter capable of stepping input voltages ranging from 4V to 30V down to 2.0V to 15V for $V_{IN} > V_{OUT}$.

The integrated high-side switch is used to chop or modulate the input voltage using a controlled duty cycle for output voltage regulation. High efficiency is achieved by using a low resistance switch, low forward drop diode, low equivalent series resistance (ESR), inductor and capacitor. When the switch is turned on, a DC voltage is applied to the inductor ($V_{IN} - V_{OUT}$), resulting in a positive linear ramp of inductor current. When the switch turns off, the applied inductor voltage is equal to $-V_{OUT}$, resulting in a negative linear ramp of inductor current (ignoring the forward drop of the Schottky diode).

For steady-state, continuous inductor current operation, the positive inductor current ramp must equal the negative current ramp in magnitude. While operating in steady state, the switch duty cycle must be equal to the relationship of V_{OUT}/V_{IN} for constant output voltage regulation, under the condition that the inductor current is continuous, or never reaches zero. For discontinuous inductor current operation, the steady-state duty cycle will be less than V_{OUT}/V_{IN} to maintain voltage regulation. The average of the

chopped input voltage or SW node voltage is equal to the output voltage, while the average of the inductor current is equal to the output current.

FIGURE 4-2: Step-Down Converter.

4.2.2 PEAK CURRENT MODE CONTROL

The MCP16301 integrates a Peak Current Mode Control architecture, resulting in superior AC regulation while minimizing the number of voltage loop compensation components, and their size, for integration. Peak Current Mode Control takes a small portion of the inductor current, replicates it and compares this replicated current sense signal with the output of the integrated error voltage. In practice, the inductor current and the internal switch current are equal during the switch-on time. By adding this peak current sense to the system control, the step-down power train system is reduced from a 2nd order to a 1st order. This reduces the system complexity and increases its dynamic performance.

For Pulse-Width Modulation (PWM) duty cycles that exceed 50%, the control system can become bimodal where a wide pulse followed by a short pulse repeats instead of the desired fixed pulse width. To prevent this mode of operation, an internal compensating ramp is summed into the current shown in [Figure 4-1](#).

4.2.3 PULSE-WIDTH MODULATION (PWM)

The internal oscillator periodically starts the switching period, which in MCP16301's case occurs every 2 μ s or 500 kHz. With the integrated switch turned on, the inductor current ramps up until the sum of the current sense and slope compensation ramp exceeds the integrated error amplifier output. The error amplifier output slews up or down to increase or decrease the inductor peak current feeding into the output LC filter. If the regulated output voltage is lower than its target, the inverting error amplifier output rises. This results in an increase in the inductor current to correct for errors in the output voltage. The fixed frequency duty cycle is terminated when the sensed inductor peak current, summed with the internal slope compensation, exceeds the output voltage of the error amplifier. The PWM latch is set by turning off the internal switch and preventing it from turning on until the beginning of the next cycle. An overtemperature signal, or boost cap undervoltage, can also reset the PWM latch to asynchronously terminate the cycle.

4.2.4 HIGH SIDE DRIVE

The MCP16301 features an integrated high-side N-Channel MOSFET for high efficiency step-down power conversion. An N-Channel MOSFET is used for its low resistance and size (instead of a P-Channel MOSFET). The N-Channel MOSFET gate must be driven above its source to fully turn on the transistor. A gate-drive voltage above the input is necessary to turn on the high side N-Channel. The high side drive voltage should be between 3.0V and 5.5V. The N-Channel source is connected to the inductor and Schottky diode, or switch node. When the switch is off, the inductor current flows through the Schottky diode, providing a path to recharge the boost cap from the boost voltage source, typically the output voltage for 3.0V to 5.0V output applications. A boost-blocking diode is used to prevent current flow from the boost cap back into the output during the internal switch-on time. Prior to startup, the boost cap has no stored charge to drive the switch. An internal regulator is used to "pre-charge" the boost cap. Once pre-charged, the switch is turned on and the inductor current flows. When the switch turns off, the inductor current free-wheels through the Schottky diode, providing a path to recharge the boost cap. Worst case conditions for recharge occur when the switch turns on for a very short duty cycle at light load, limiting the inductor current ramp. In this case, there is a small amount of time for the boost capacitor to recharge. For high input voltages there is enough pre-charge current to replace the boost cap charge. For input voltages above 5.5V typical, the MCP16301 device will regulate the output voltage with no load. After starting, the MCP16301 will regulate the output voltage until the input voltage decreases below 4V. See [Figure 2-16](#) for device range of operation over input voltage, output voltage and load.

4.2.5 ALTERNATIVE BOOST BIAS

For 3.0V to 5.0V output voltage applications, the boost supply is typically the output voltage. For applications with $3.0V < V_{OUT} < 5.0V$, an alternative boost supply can be used.

Alternative boost supplies can be from the input, input derived, output derived or an auxiliary system voltage.

For low voltage output applications with unregulated input voltage, a shunt regulator derived from the input can be used to derive the boost supply. For applications with high output voltage or regulated high input voltage, a series regulator can be used to derive the boost supply.

MCP16301

FIGURE 4-3: Shunt and External Boost Supply.

Shunt Boost Supply Regulation is used for low output voltage converters operating from a wide ranging input source. A regulated 3.0V to 5.5V supply is needed to provide high side-drive bias. The shunt uses a Zener diode to clamp the voltage within the 3.0V to 5.5V range using the resistance shown in [Figure 4-3](#).

To calculate the shunt resistance, the boost drive current can be estimated using [Equation 4-1](#).

I_{BOOST_TYP} for 3.3V Boost Supply = 0.6 mA

I_{BOOST_TYP} for 5.0V Boost Supply = 0.8 mA.

EQUATION 4-1: BOOST CURRENT

$$I_{BOOST} = I_{BOOST_TYP} \times 1.5mA$$

To calculate the shunt resistance, the maximum I_{BOOST} and I_Z current are used at the minimum input voltage (Equation 4-2).

V_Z and I_Z can be found on the Zener diode manufacturer's data sheet. Typical $I_Z = 1\text{ mA}$.

EQUATION 4-2: SHUNT RESISTANCE

$$R_{SH} = \frac{V_{INMIN} - V_Z}{I_{Boost} + I_Z}$$

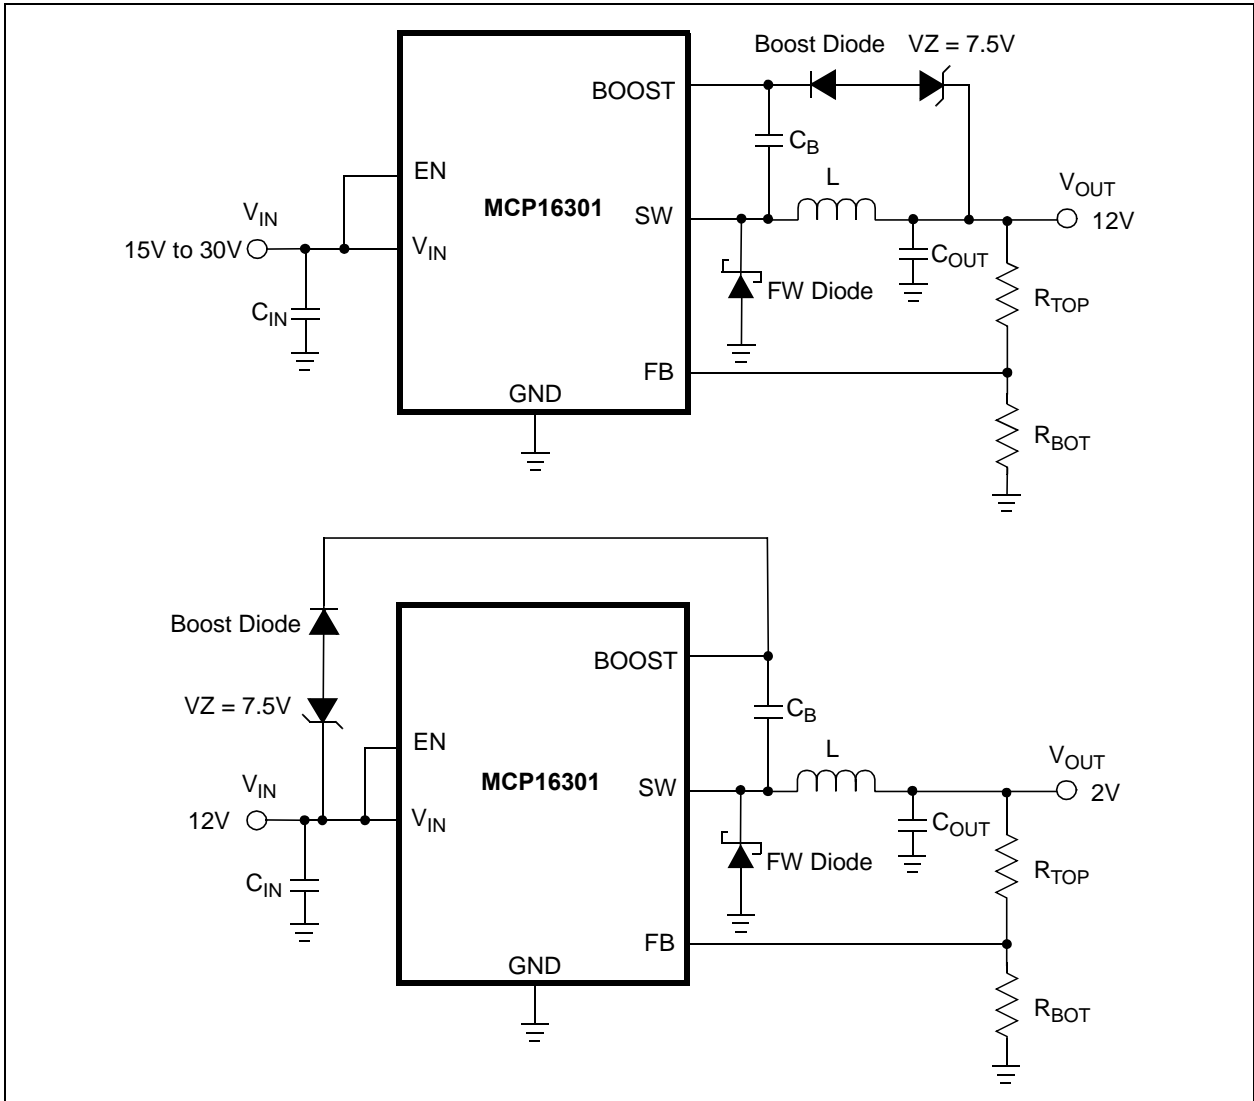

FIGURE 4-4: Series Regulator Boost Supply.

Series regulator applications use a Zener diode to drop the excess voltage. The series regulator bias source can be input or output voltage derived, as shown in Figure 4-4. The boost supply must remain between 3.0V and 5.5V at all times for proper circuit operation.

MCP16301

NOTES:

5.0 APPLICATION INFORMATION

5.1 Typical Applications

The MCP16301 step-down converter operates over a wide input voltage range, up to 30V maximum. Typical applications include generating a bias or V_{DD} voltage for the PIC[®] microcontrollers product line, digital control system bias supply for AC-DC converters, 24V industrial input and similar applications.

5.2 Adjustable Output Voltage Calculations

To calculate the resistor divider values for the MCP16301, Equation 5-1 can be used. R_{TOP} is connected to V_{OUT} , R_{BOT} is connected to GND and both are connected to the V_{FB} input pin.

EQUATION 5-1:

$$R_{TOP} = R_{BOT} \times \left(\frac{V_{OUT}}{V_{FB}} - 1 \right)$$

EXAMPLE 5-1:

$$\begin{aligned} V_{OUT} &= 3.3V \\ V_{FB} &= 0.8V \\ R_{BOT} &= 10 \text{ k}\Omega \\ R_{TOP} &= 31.25 \text{ k}\Omega \text{ (Standard Value = 31.2 k}\Omega\text{)} \\ V_{OUT} &= 3.3V \end{aligned}$$

EXAMPLE 5-2:

$$\begin{aligned} V_{OUT} &= 5.0V \\ V_{FB} &= 0.8V \\ R_{BOT} &= 10 \text{ k}\Omega \\ R_{TOP} &= 52.5 \text{ k}\Omega \text{ (Standard Value = 52.3 k}\Omega\text{)} \\ V_{OUT} &= 4.98V \end{aligned}$$

The transconductance error amplifier gain is controlled by its internal impedance. The external divider resistors have no effect on system gain, so a wide range of values can be used. A 10 k Ω resistor is recommended as a good trade-off for quiescent current and noise immunity.

5.3 General Design Equations

The step down converter duty cycle can be estimated using Equation 5-2, while operating in Continuous Inductor Current Mode. This equation also counts the forward drop of the freewheeling diode and internal N-Channel MOSFET switch voltage drop. As the load current increases, the switch voltage drop and diode voltage drop increase, requiring a larger PWM duty cycle to maintain the output voltage regulation. Switch voltage drop is estimated by multiplying the switch current times the switch resistance or $R_{DS(ON)}$.

EQUATION 5-2: CONTINUOUS INDUCTOR CURRENT DUTY CYCLE

$$D = \frac{(V_{OUT} + V_{Diode})}{(V_{IN} - (I_{SW} \times R_{DS(ON)})}$$

The MCP16301 device features an integrated slope compensation to prevent the bimodal operation of the PWM duty cycle. Internally, half of the inductor current down slope is summed with the internal current sense signal. For the proper amount of slope compensation, it is recommended to keep the inductor down-slope current constant by varying the inductance with V_{OUT} , where $K = 0.22V/\mu H$.

EQUATION 5-3:

$$K = V_{OUT}/L$$

For $V_{OUT} = 3.3V$, an inductance of 15 μH is recommended.

TABLE 5-1: RECOMMENDED INDUCTOR VALUES

V_{OUT}	K	$L_{STANDARD}$
2.0V	0.20	10 μH
3.3V	0.22	15 μH
5.0V	0.23	22 μH
12V	0.21	56 μH
15V	0.22	68 μH

MCP16301

5.4 Input Capacitor Selection

The step-down converter input capacitor must filter the high input ripple current, as a result of pulsing or chopping the input voltage. The MCP16301 input voltage pin is used to supply voltage for the power train and as a source for internal bias. A low equivalent series resistance (ESR), preferably a ceramic capacitor, is recommended. The necessary capacitance is dependent upon the maximum load current and source impedance. Three capacitor parameters to keep in mind are the voltage rating, equivalent series resistance and the temperature rating. For wide temperature range applications, a multi-layer X7R dielectric is recommended, while for applications with limited temperature range, a multi-layer X5R dielectric is acceptable. Typically, input capacitance between 4.7 μF and 10 μF is sufficient for most applications. For applications with 100 mA to 200 mA load, a 1 μF X7R capacitor can be used, depending on the input source and its impedance.

The input capacitor voltage rating should be a minimum of V_{IN} plus margin. Table 5-2 contains the recommended range for the input capacitor value.

5.5 Output Capacitor Selection

The output capacitor helps in providing a stable output voltage during sudden load transients, and reduces the output voltage ripple. As with the input capacitor, X5R and X7R ceramic capacitors are well suited for this application.

The MCP16301 is internally compensated, so the output capacitance range is limited. See Table 5-2 for the recommended output capacitor range.

The amount and type of output capacitance and equivalent series resistance will have a significant effect on the output ripple voltage and system stability. The range of the output capacitance is limited due to the integrated compensation of the MCP16301.

The output voltage capacitor voltage rating should be a minimum of V_{OUT} , plus margin.

Table 5-2 contains the recommended range for the input and output capacitor value:

TABLE 5-2: CAPACITOR VALUE RANGE

Parameter	Min	Max
C_{IN}	2.2 μF	none
C_{OUT}	20 μF	none

5.6 Inductor Selection

The MCP16301 is designed to be used with small surface mount inductors. Several specifications should be considered prior to selecting an inductor. To optimize system performance, the inductance value is determined by the output voltage (Table 5-1) so the inductor ripple current is somewhat constant over the output voltage range.

EQUATION 5-4: INDUCTOR RIPPLE CURRENT

$$\Delta I_L = \frac{V_L}{L} \times t_{\text{ON}}$$

EXAMPLE 5-3:

$$\begin{aligned} V_{\text{IN}} &= 12\text{V} \\ V_{\text{OUT}} &= 3.3\text{V} \\ I_{\text{OUT}} &= 600\text{ mA} \end{aligned}$$

EQUATION 5-5: INDUCTOR PEAK CURRENT

$$I_{\text{LPK}} = \frac{\Delta I_L}{2} + I_{\text{OUT}}$$

$$\begin{aligned} \text{Inductor ripple current} &= 319\text{ mA} \\ \text{Inductor peak current} &= 760\text{ mA} \end{aligned}$$

An inductor saturation rating minimum of 760 mA is recommended. Low ESR inductors result in higher system efficiency. A trade-off between size, cost and efficiency is made to achieve the desired results.

TABLE 5-3: MCP16301 RECOMMENDED 3.3V INDUCTORS

Part Number	Value (µH)	DCR (Ω)	I _{SAT} (A)	Size WxLxH (mm)

5.7 Freewheeling Diode

The freewheeling diode creates a path for inductor current flow after the internal switch is turned off. The average diode current is dependent upon output load current at duty cycle (D). The efficiency of the converter is a function of the forward drop and speed of the freewheeling diode. A low forward drop Schottky diode is recommended. The current rating and voltage rating of the diode is application dependent. The diode voltage rating should be a minimum of V_{IN}, plus margin. For example, a diode rating of 40V should be used for an application with a maximum input of 30V. The average diode current can be calculated using [Equation 5-6](#).

EQUATION 5-6: DIODE AVERAGE CURRENT

$$I_{D1AVG} = (1 - D) \times I_{OUT}$$

EXAMPLE 5-4:

I _{OUT}	=	0.5A
V _{IN}	=	15V
V _{OUT}	=	5V
D	=	5/15
I _{D1AVG}	=	333 mA

A 0.5A to 1A diode is recommended.

TABLE 5-4: FREEWHEELING DIODES

App	Manufacturer	Part Number	Rating
12 V _{IN} 600 mA	Diodes Inc.	DFLS120L-7	20V, 1A
24 V _{IN} 100 mA	Diodes Inc.	B0540Ws-7	40V, 0.5A
18 V _{IN} 600 mA	Diodes Inc.	B130L-13-F	30V, 1A

5.8 Boost Diode

The boost diode is used to provide a charging path from the low voltage gate drive source, while the switch node is low. The boost diode blocks the high voltage of the switch node from feeding back into the output voltage when the switch is turned on, forcing the switch node high.

A standard 1N4148 ultra-fast diode is recommended for its recovery speed, high voltage blocking capability, availability and cost. The voltage rating required for the boost diode is V_{IN}.

For low boost voltage applications, a small Schottky diode with the appropriately rated voltage can be used to lower the forward drop, increasing the boost supply for gate drive.

MCP16301

5.9 Boost Capacitor

The boost capacitor is used to supply current for the internal high side drive circuitry that is above the input voltage. The boost capacitor must store enough energy to completely drive the high side switch on and off. A 0.1 μF X5R or X7R capacitor is recommended for all applications. The boost capacitor maximum voltage is 5.5V, so a 6.3V or 10V rated capacitor is recommended.

5.10 Thermal Calculations

The MCP16301 is available in a SOT-23-6 package. By calculating the power dissipation and applying the package thermal resistance (θ_{JA}), the junction temperature is estimated. The maximum continuous junction temperature rating for the MCP16301 is +125°C.

To quickly estimate the internal power dissipation for the switching step-down regulator, an empirical calculation using measured efficiency can be used. Given the measured efficiency, the internal power dissipation is estimated by Equation 5-7. This power dissipation includes all internal and external component losses. For a quick internal estimate, subtract the estimated Schottky diode loss and inductor ESR loss from the P_{DIS} calculation in Equation 5-7.

EQUATION 5-7: TOTAL POWER DISSIPATION ESTIMATE

$$\left(\frac{V_{OUT} \times I_{OUT}}{\text{Efficiency}}\right) - (V_{OUT} \times I_{OUT}) = P_{Dis}$$

The difference between the first term, input power, and the second term, power delivered, is the total system power dissipation. The freewheeling Schottky diode losses are determined by calculating the average diode current and multiplying by the diode forward drop. The inductor losses are estimated by $P_L = I_{OUT}^2 \times L_{ESR}$.

EQUATION 5-8: DIODE POWER DISSIPATION ESTIMATE

$$P_{Diode} = V_F \times ((1 - D) \times I_{OUT})$$

EXAMPLE 5-5:

V_{IN}	=	10V
V_{OUT}	=	5.0V
I_{OUT}	=	0.4A
Efficiency	=	90%
Total System Dissipation	=	222 mW
L_{ESR}	=	0.15 Ω
P_L	=	24 mW
Diode VF	=	0.50
D	=	50%
P_{Diode}	=	125 mW

MCP16301 internal power dissipation estimate:

$$P_{DIS} - P_L - P_{DIODE} = 73 \text{ mW}$$

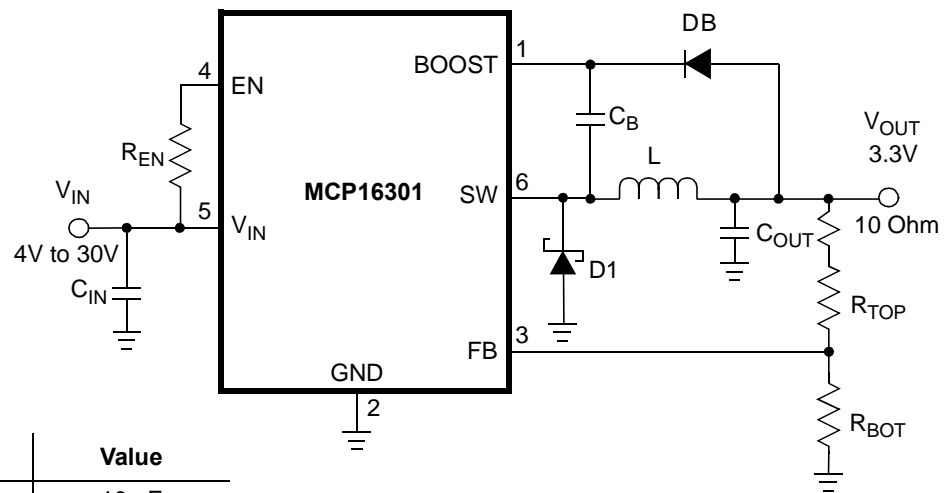

θ_{JA}	=	198°C/W
Estimated Junction Temperature Rise	=	+14.5°C

5.11 PCB Layout Information

Good printed circuit board layout techniques are important to any switching circuitry, and switching power supplies are no different. When wiring the switching high-current paths, short and wide traces should be used. Therefore, it is important that the input and output capacitors be placed as close as possible to the MCP16301 to minimize the loop area.

The feedback resistors and feedback signal should be routed away from the switching node and the switching current loop. When possible, ground planes and traces should be used to help shield the feedback signal and minimize noise and magnetic interference.

A good MCP16301 layout starts with C_{IN} placement. C_{IN} supplies current to the input of the circuit when the switch is turned on. In addition to supplying high-frequency switch current, C_{IN} also provides a stable voltage source for the internal MCP16301 circuitry. Unstable PWM operation can result if there are excessive transients or ringing on the V_{IN} pin of the MCP16301 device. In Figure 5-1, C_{IN} is placed close to pin 5. A ground plane on the bottom of the board provides a low resistive and inductive path for the return current. The next priority in placement is the freewheeling current loop formed by D1, C_{OUT} and L, while strategically placing C_{OUT} return close to C_{IN} return. Next, C_B and D_B should be placed between the boost pin and the switch node pin SW. This leaves space close to the MCP16301 V_{FB} pin to place R_{TOP} and R_{BOT} . R_{TOP} and R_{BOT} are routed away from the Switch node so noise is not coupled into the high-impedance V_{FB} input.

Component	Value
C_{IN}	10 μ F
C_{OUT}	2 x 10 μ F
L	15 μ H
R_{TOP}	31.2 k Ω
R_{BOT}	10 k Ω
D1	B140
D_B	1N4148
C_B	100 nF

***Note:** 10 Ohm resistor is used with network analyzer, to measure system gain and phase.

NOTES:

7.0 PACKAGING INFORMATION

7.1 Package Marking Information

6-Lead SOT-23

Example

Legend:	XX...X	Customer-specific information
	Y	Year code (last digit of calendar year)
	YY	Year code (last 2 digits of calendar year)
	WW	Week code (week of January 1 is week '01')
	NNN	Alphanumeric traceability code
	(e3)	Pb-free JEDEC designator for Matte Tin (Sn)
	*	This package is Pb-free. The Pb-free JEDEC designator (e3) can be found on the outer packaging for this package.

Note: In the event the full Microchip part number cannot be marked on one line, it will be carried over to the next line, thus limiting the number of available characters for customer-specific information.

MCP16301

6-Lead Plastic Small Outline Transistor (CHY) [SOT-23]

Note: For the most current package drawings, please see the Microchip Packaging Specification located at <http://www.microchip.com/packaging>

Dimension Limits	Units	MILLIMETERS		
		MIN	NOM	MAX
Number of Pins	N	6		
Pitch	e	0.95 BSC		
Outside Lead Pitch	e1	1.90 BSC		
Overall Height	A	0.90	–	1.45
Molded Package Thickness	A2	0.89	–	1.30
Standoff	A1	0.00	–	0.15
Overall Width	E	2.20	–	3.20
Molded Package Width	E1	1.30	–	1.80
Overall Length	D	2.70	–	3.10
Foot Length	L	0.10	–	0.60
Footprint	L1	0.35	–	0.80
Foot Angle	ϕ	0°	–	30°
Lead Thickness	c	0.08	–	0.26
Lead Width	b	0.20	–	0.51

Notes:

- Dimensions D and E1 do not include mold flash or protrusions. Mold flash or protrusions shall not exceed 0.127 mm per side.
- Dimensioning and tolerancing per ASME Y14.5M.

BSC: Basic Dimension. Theoretically exact value shown without tolerances.

NOTES:

Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable.”

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer's risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights.

Microchip received ISO/TS-16949:2002 certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona; Gresham, Oregon and design centers in California and India. The Company's quality system processes and procedures are for its PIC[®] MCUs and dsPIC[®] DSCs, KEELOQ[®] code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip's quality system for the design and manufacture of development systems is ISO 9001:2000 certified.
