

## High Accuracy, Hall-effect Based Current Sensor IC in High Isolation SOIC16 Package

### FEATURES AND BENEFITS

- Patented integrated digital temperature compensation circuitry allows for near closed loop accuracy over temperature in an open loop sensor
- UL60950-1 (ed. 2) certified
  - Dielectric Strength Voltage = 4.8 kVrms
  - Basic Isolation Working Voltage = 1097 Vrms
  - Reinforced Isolation Working Voltage = 565 Vrms
- Industry-leading noise performance with greatly improved bandwidth through proprietary amplifier and filter design techniques
- Pin-selectable band width: 80 kHz for high bandwidth applications or 20 kHz for low noise performance
- 0.85 mΩ primary conductor resistance for low power loss and high inrush current withstand capability
- Low-profile SOIC16 package suitable for space-constrained applications
- 3 to 3.6 V, single supply operation
- Output voltage proportional to AC or DC current
- Factory-trimmed sensitivity and quiescent output voltage for improved accuracy

### Package: 16-pin SOICW (suffix MA)

Approximate Scale 1:1

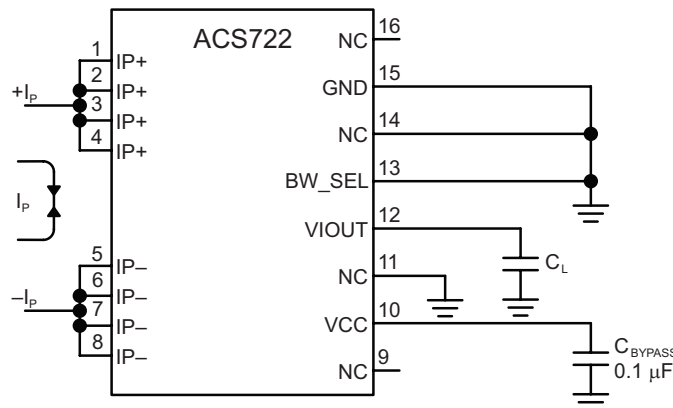

### DESCRIPTION

The Allegro™ ACS722 current sensor IC is an economical and precise solution for AC or DC current sensing in industrial, commercial, and communication systems. The small package is ideal for space constrained applications while also saving costs due to reduced board area. Typical applications include motor control, load detection and management, switched-mode power supplies, and overcurrent fault protection.

The device consists of a precise, low-offset, linear Hall sensor circuit with a copper conduction path located near the surface of the die. Applied current flowing through this copper conduction path generates a magnetic field which is sensed by the integrated Hall IC and converted into a proportional voltage. Device accuracy is optimized through the close proximity of the magnetic field to the Hall transducer. A precise, proportional voltage is provided by the low-offset, chopper-stabilized BiCMOS Hall IC, which includes Allegro's patented digital temperature compensation, resulting in extremely accurate performance over temperature. The output of the device has a positive slope when an increasing current flows through the primary copper conduction path (from pins 1 through 4, to pins 5 through 8), which is the path used for current sensing. The internal resistance of this conductive path is 0.85 mΩ typical, providing low power loss.

The terminals of the conductive path are electrically isolated from the sensor leads (pins 9 through 16). This allows the ACS722 current sensor IC to be used in high-side current sense applications without the use of high-side differential amplifiers or other costly isolation techniques.

Continued on the next page...

Typical Application

The ACS722 outputs an analog signal,  $V_{IOUT}$ , that changes, proportionally, with the bidirectional AC or DC primary sensed current,  $I_p$ , within the specified measurement range. The BW\_SEL pin can be used to select one of the two bandwidths to optimize the noise performance. Grounding the BW\_SEL pin puts the part in the high bandwidth (80 kHz) mode.

---

## Features and Benefits (continued)

- Chopper stabilization results in extremely stable quiescent output voltage
- Nearly zero magnetic hysteresis
- Ratiometric output from supply voltage

## Description (continued)

The ACS722 is provided in a low profile surface mount SOIC16 package. The leadframe is plated with 100% matte tin, which is compatible with standard lead (Pb) free printed circuit board assembly processes. Internally, the device is Pb-free, except for flip-chip high-temperature Pb-based solder balls, currently exempt from RoHS. The device is fully calibrated prior to shipment from the factory.

## Selection Guide

Part Number	I <sub>PR</sub> (A)	Sens(Typ) at V <sub>CC</sub> = 3.3 V (mV/A)	T <sub>A</sub> (°C)	Packing <sup>1</sup>
ACS722KMATR-10AB-T	±10	132	-40 to 125	Tape and Reel, 3000 pieces per reel
ACS722KMATR-20AB-T	±20	66		
ACS722KMATR-40AB-T	±40	33

## SPECIFICATIONS

### Absolute Maximum Ratings

Characteristic	Symbol	Notes	Rating	Units
Supply Voltage	$V_{CC}$		6	V
Reverse Supply Voltage	$V_{RCC}$		-0.1	V
Output Voltage	$V_{IOUT}$		25	V
Reverse Output Voltage	$V_{RIOUT}$		-0.1	V
Operating Ambient Temperature	$T_A$	Range K	-40 to 125	°C
Junction Temperature	$T_J(\text{max})$		165	°C
Storage Temperature	$T_{stg}$		-65 to 165	°C

### Isolation Characteristics

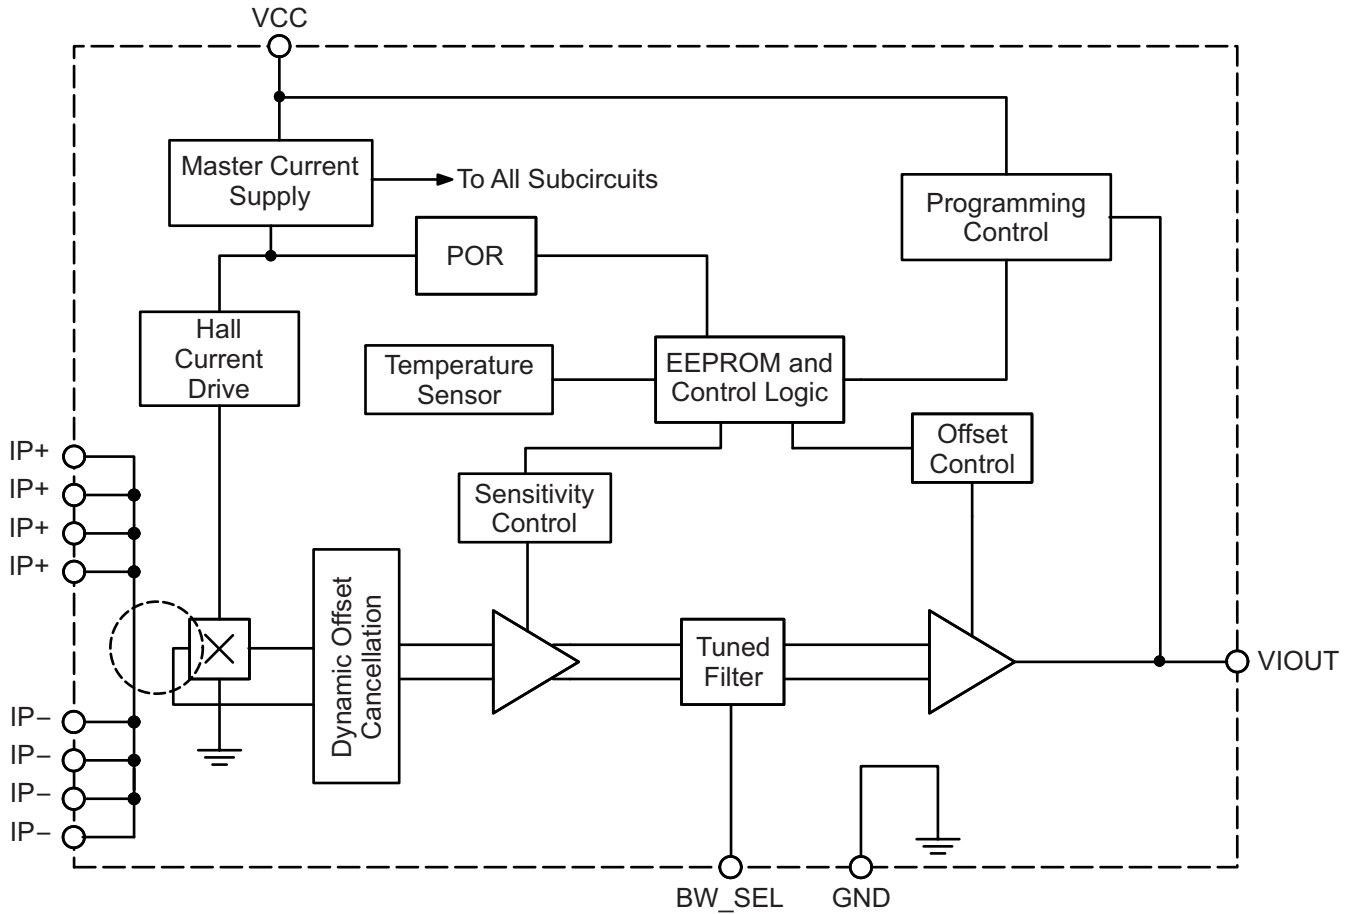

Characteristic	Symbol	Notes	Rating	Unit
Dielectric Strength Test Voltage	$V_{ISO}$	Agency type-tested for 60 seconds per UL 60950-1 (edition. 2). Production tested at 3000 $V_{RMS}$ for 1 second, in accordance with UL 60950-1 (edition. 2).	4800	$V_{RMS}$
Working Voltage for Basic Isolation	$V_{WVBI}$	Maximum approved working voltage for basic (single) isolation according UL 60950-1 (edition 2)	1550	$V_{PK}$
			1097	$V_{RMS}$ or VDC
Working Voltage for Reinforced Isolation	$V_{WVRI}$	Maximum approved working voltage for reinforced isolation according to UL 60950-1 (edition 2)	800	$V_{PK}$
			565	$V_{RMS}$ or VDC
Clearance	$D_{cl}$	Minimum distance through air from IP leads to signal leads.	7.5	mm
Creepage	$D_{cr}$	Minimum distance along package body from IP leads to signal leads	8.2	mm

### Thermal Characteristics

Characteristic	Symbol	Test Conditions*	Value	Units
Package Thermal Resistance (Junction to Ambient)	$R_{\theta JA}$	Mounted on the Allegro 85-0738 evaluation board with 700 mm <sup>2</sup> of 4 oz. copper on each side, connected to pins 1 and 2, and to pins 3 and 4, with thermal vias connecting the layers. Performance values include the power consumed by the PCB.	23	°C/W
Package Thermal Resistance (Junction to Lead)	$R_{\theta JL}$	Mounted on the Allegro ASEK 722 evaluation board.	5	°C/W

\*Additional thermal information available on the Allegro website.

## DEFINITIONS OF ACCURACY CHARACTERISTICS

### Sensitivity (Sens)

The change in sensor IC output in response to a 1A change through the primary conductor. The sensitivity is the product of the magnetic coupling factor (G/A) (1 G = 0.1 mT) and the linear IC amplifier gain (mV/G). The linear IC amplifier gain is programmed at the factory to optimize the sensitivity (mV/A) for the full-scale current of the device.

### Nonlinearity ( $E_{LIN}$ )

The nonlinearity is a measure of how linear the output of the sensor IC is over the full current measurement range. The nonlinearity is calculated as:

$$E_{LIN} = \left\{ 1 - \left[ \frac{V_{IOUT}(I_{PR(max)}) - V_{IOUT(Q)}}{2 \times V_{IOUT}(I_{PR(max)/2}) - V_{IOUT(Q)}} \right] \right\} \times 100 (\%)$$

where  $V_{IOUT}(I_{PR(max)})$  is the output of the sensor IC with the maximum measurement current flowing through it and  $V_{IOUT}(I_{PR(max)/2})$  is the output of the sensor IC with half of the maximum measurement current flowing through it.

### Zero Current Output Voltage ( $V_{IOUT(Q)}$ )

The output of the sensor when the primary current is zero. For a unipolar supply voltage, it nominally remains at  $0.5 \times V_{CC}$  for a bidirectional device and  $0.1 \times V_{CC}$  for a unidirectional device. For example, in the case of a bidirectional output device,  $V_{CC} = 3.3 \text{ V}$  translates into  $V_{IOUT(Q)} = 1.65 \text{ V}$ . Variation in  $V_{IOUT(Q)}$  can be attributed to the resolution of the Allegro linear IC quiescent voltage trim and thermal drift.

### Offset Voltage ( $V_{OE}$ )

The deviation of the device output from its ideal quiescent value of  $0.5 \times V_{CC}$  (bidirectional) or  $0.1 \times V_{CC}$  (unidirectional) due to nonmagnetic causes. To convert this voltage to amperes, divide by the device sensitivity, Sens.

### Total Output Error ( $E_{TOT}$ )

The the difference between the current measurement from the sensor IC and the actual current ( $I_p$ ), relative to the actual current. This is equivalent to the difference between the ideal output voltage and the actual output voltage, divided by the ideal sensitivity, relative to the current flowing through the primary conduction path:

$$E_{TOT}(I_p) = \frac{V_{IOUT\_ideal}(I_p) - V_{IOUT}(I_p)}{\text{Sens}_{ideal}(I_p) \times I_p} \times 100 (\%)$$

The Total Output Error incorporates all sources of error and is a function of  $I_p$ . At relatively high currents,  $E_{TOT}$  will be mostly

due to sensitivity error, and at relatively low currents,  $E_{TOT}$  will be mostly due to Offset Voltage ( $V_{OE}$ ). In fact, at  $I_p = 0$ ,  $E_{TOT}$  approaches infinity due to the offset. This is illustrated in Figures 1 and 2. Figure 1 shows a distribution of output voltages versus  $I_p$  at  $25^\circ\text{C}$  and across temperature. Figure 2 shows the corresponding  $E_{TOT}$  versus  $I_p$ .

Figure 1: Output Voltage versus Sensed Current

Figure 2: Total Output Error versus Sensed Current

## APPLICATION INFORMATION

### Impact of External Magnetic Fields

The ACS722 works by sensing the magnetic field created by the current flowing through the package. However, the sensor cannot differentiate between fields created by the current flow and external magnetic fields. This means that external magnetic fields can cause errors in the output of the sensor. Magnetic fields which are perpendicular to the surface of the package affect the output of the sensor, as it only senses fields in that one plane. The error in Amperes can be quantified as:

$$Error(B) = \frac{B}{C_F}$$

where B is the strength of the external field perpendicular to the surface of the package in Gauss, and C<sub>F</sub> is the coupling factor in G/A. Then, multiplying by the sensitivity of the part (Sens) gives the error in mV.

For example, an external field of 1 Gauss will result in around 0.22 A of error. If the ACS722KMATR-10AB, which has a nominal sensitivity of 132 mV/A, is being used, that equates to 29 mV of error on the output of the sensor.

**Table 1: External Magnetic Field (Gauss) Impact**

External Field (Gauss)	Error (A)	Error (mV)		
		10AB	20AB	40AB
0.5	0.11	15	7	4
1	0.22	29	15	7
2	0.44	58	29	15

### Estimating Total Error vs. Sensed Current

The Performance Characteristics tables give distribution (±3 sigma) values for Total Error at I<sub>PR(max)</sub>; however, one often wants to know what error to expect at a particular current. This can be estimated by using the distribution data for the components of Total Error, Sensitivity Error and Offset Voltage. The

±3 sigma value for Total Error (E<sub>TOT</sub>) as a function of the sensed current (I<sub>P</sub>) is estimated as:

$$E_{TOT}(I_P) = \sqrt{E_{SENS}^2 + \left(\frac{100 \times V_{OE}}{Sens \times I_P}\right)^2}$$

Here, E<sub>SENS</sub> and V<sub>OE</sub> are the ±3 sigma values for those error terms. If there is an average sensitivity error or average offset voltage, then the average Total Error is estimated as:

$$E_{TOT,AVG}(I_P) = E_{SENS,AVG} + \frac{100 \times V_{OE,AVG}}{Sens \times I_P}$$

The resulting total error will be a sum of E<sub>TOT</sub> and E<sub>TOT,AVG</sub>. Using these equations and the 3 sigma distributions for Sensitivity Error and Offset Voltage, the Total Error vs. sensed current (I<sub>P</sub>) is below for the ACS722KMATR-40AB. As expected, as one goes towards zero current, the error in percent goes towards infinity due to division by zero (refer to Figure 3)

**Figure 3: Predicted Total Error as a Function of Sensed Current for the ACS722KMATR-40AB**

## DEFINITIONS OF DYNAMIC RESPONSE CHARACTERISTICS

### Power-On Time ( $t_{PO}$ )

When the supply is ramped to its operating voltage, the device requires a finite time to power its internal components before responding to an input magnetic field.

Power-On Time ( $t_{PO}$ ) is defined as the time it takes for the output voltage to settle within  $\pm 10\%$  of its steady state value under an applied magnetic field, after the power supply has reached its minimum specified operating voltage ( $V_{CC(min)}$ ) as shown in the chart at right (refer to Figure 4).

### Rise Time ( $t_r$ )

The time interval between: a) when the sensor IC reaches 10% of its full scale value; and b) when it reaches 90% of its full scale value (refer to Figure 5). The rise time to a step response is used to derive the bandwidth of the current sensor IC, in which  $f(-3 \text{ dB}) = 0.35/t_r$ . Both  $t_r$  and  $t_{RESPONSE}$  are detrimentally affected by eddy current losses observed in the conductive IC ground plane.

### Propagation Delay ( $t_{pd}$ )

The propagation delay is measured as the time interval between: a) when the primary current signal reaches 20% of its final value; and b) when the device reaches 20% of its output corresponding to the applied current (refer to Figure 5).

### Response Time ( $t_{RESPONSE}$ )

The time interval between: a) when the primary current signal reaches 90% of its final value; and b) when the device reaches 90% of its output corresponding to the applied current (refer to Figure 6).

Figure 4: Power-On Time

Figure 5: Rise Time and Propagation Delay
