## FEATURES

Quad 2:1 mux/1:2 demux
Optimized for dc to 6.5 Gbps NRZ data
Per-lane P/N pair inversion for routing ease
Programmable input equalization
Compensates up to 40 inches of FR4

## Loss-of-signal detection

Programmable output pre-emphasis up to 12 dB Programmable output levels with squelch and disable
Accepts ac-coupled or dc-coupled differential CML inputs
$50 \Omega$ on-chip termination
1:2 demux supports unicast or bicast operation
Port-level loopback
Port or single lane switching
1.8 V to 3.3 V flexible core supply

User-settable I/O supply from $\mathrm{V}_{\mathrm{cc}}$ to 1.2 V
Low power, typically 2.0 W in basic configuration 100-lead LFCSP
$-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ operating temperature range

## APPLICATIONS

## Low cost redundancy switch

SONET OC48/SDH16 and lower data rates
XAUI/GbE/FC/Infiniband over backplane
OIF CEI 6.25 Gbps over backplane
Serial data-level shift
4-/8-/12-lane equalizers or redrivers

## GENERAL DESCRIPTION

The AD8158 is an asynchronous, protocol-agnostic, quad-lane 2:1 switch with a total of 12 differential CML inputs and 12 differential CML outputs. The signal path supports NRZ signaling with data rates up to 6.5 Gbps per lane. Each lane offers programmable receive equalization, programmable output pre-emphasis, programmable output levels, and loss-ofsignal detection.
The nonblocking switch-core of the AD8158 implements a 2:1 multiplexer and 1:2 demultiplexer per lane and supports independent lane switching through the four select pins, SEL[3:0]. Each port is a four-lane link. Every lane implements an asynchronous path supporting dc to 6.5 Gbps NRZ data, fully independent of other lanes. The AD8158 has low latency and very low lane-to-lane skew.
The main application of the AD8158 is to support redundancy on both the backplane and the line interface sides of a serial link. The demultiplexing path implements unicast and bicast

## FUNCTIONAL BLOCK DIAGRAM

Figure 1.
capability, allowing the part to support either $1+1$ or 1:1 redundancy.
The AD8158 is also suited for testing high speed serial links because of its ability to duplicate incoming data. In a portmonitoring application, the AD8158 can maintain linkconnectivity with a pass-through connection from Port C to Port A while sending a duplicate copy of the data to test equipment on Port B.
The rich feature set of the AD8158 can be controlled either through external toggle pins or by setting on-chip control registers through the $\mathrm{I}^{2} \mathrm{C}^{\otimes}$ interface.

## ABSOLUTE MAXIMUM RATINGS

Table 3.

| Parameter | Rating |
| :--- | :--- |
| $\mathrm{V}_{\mathrm{CC}}$ to $\mathrm{V}_{\mathrm{EE}}$ | 3.7 V |
| DV CCC to $\mathrm{V}_{\mathrm{EE}}$ | 3.7 V |
| $\mathrm{~V}_{\mathrm{TTI}}$ | Lower of $\left(\mathrm{V}_{\mathrm{CC}}+0.6 \mathrm{~V}\right)$ or 3.6 V |
| $\mathrm{~V}_{\mathrm{TTO}}$ | Lower of $(\mathrm{V} \mathrm{CC}+0.6 \mathrm{~V})$ or 3.6 V |
| $\mathrm{~V}_{\mathrm{CC}}$ to $\mathrm{DV} \mathrm{V}_{\mathrm{CC}}$ | 0.6 V |
| Internal Power Dissipation | 4.26 W |
| Differential Input Voltage | 2.0 V |
| Logic Input Voltage | $\mathrm{V}_{\mathrm{EE}}-0.3 \mathrm{~V}<\mathrm{V}_{\mathrm{IN}}<\mathrm{V}_{\mathrm{CC}}+0.6 \mathrm{~V}$ |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Lead Temperature | $300^{\circ} \mathrm{C}$ |

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## THEORY OF OPERATION

The AD8158 is a buffered, asynchronous, three-port transceiver that allows 2:1 multiplexing and 1:2 demultiplexing among its ports. The 1:2 demux path supports bicast operation, allowing the AD8158 to operate as a port replicator as well as a redundancy switch. The AD8158 offers loopback on each lane, allowing the part to be configured as a 12-lane equalizer or redriver with FFE.

Figure 35. Mux/Demux Paths, Port A to Port C
The part offers extensively programmable transmit output levels and pre-emphasis settings as well as squelch or full-disable. The receivers integrate a programmable, multizero transfer function for aggressive equalization and a programmable loss-of-signal feature. The AD8158 provides a balanced, high speed switch core that maintains low lane-to-lane skew while preserving edge rates.

The I/O on-chip termination resistors are tied to user-settable supplies for increased flexibility. The AD8158 supports a wide primary supply range; $\mathrm{V}_{\mathrm{CC}}$ can be set from 1.8 V to 3.3 V . These features, together with programmable transmitter output levels, allow for a wide range of dc- and ac-coupled I/O configurations.
The AD8158 supports several control and configuration modes, shown in Table 5.

Table 5. Control Modes

| Mode | Description |
| :--- | :--- |
| Toggle Pin <br> Control | Asynchronous control through toggle pins only |
| Mixed Control | Switch configuration via toggle pins, register- <br> based control through the $I^{2} C$ serial interface |
| Serial Control | Register-based control through the $I^{2} C$ serial <br> interface |

The pin control mode offers access to a subset of the total feature list but allows for a much simplified control scheme. Table 6 compares the available features in all control modes.

The primary advantage of using the serial control interface is that it allows finer resolution in setting receive equalization, transmitter pre-emphasis, loss-of-signal (LOS) behavior, and output levels.
By default, the AD8158 starts in the pin control mode. Strobing the RESETb pin sets all on-chip registers to their default values and uses pins to configure switch connectivity, PE, and EQ levels. In mixed mode, switch connectivity is still controlled through the SEL[3:0], LB_[A:C], and BICAST pins. The user can override PE and EQ settings in mixed mode. In serial mode, all functions are accessed through registers and the control pin inputs are ignored, except RESETb. Register 0x0F selects the control mode (see Table 7).
The AD8158 register set is controlled through a 2 -wire $\mathrm{I}^{2} \mathrm{C}$ interface. The AD8158 acts only as an $\mathrm{I}^{2} \mathrm{C}$ slave device. The 7 -bit slave address for the $\mathrm{AD} 8158 \mathrm{I}^{2} \mathrm{C}$ interface contains the static value b1010 for the upper four bits. The lower three bits are controlled by the input pins I2C_A[2:0].

Table 6. Features Available Through Toggle Pin or Serial Control

| Feature | Pin Control | Serial Control |
| :--- | :--- | :--- |
| Switch Features |  |  |
| BICAST | One pin | One bit |
| A/B Lane Select | Four pins | Four bits |
| Loopback | Three pins | Three bits |
| Rx Features |  |  |
| EQ Levels | Four settings | 10 settings |
| N/P Swap | Not available | Available |

Table 8. Setting the Control Interface Mode

| Mode 1 | Mode 0 | Control Mode |
| :--- | :--- | :--- |
| 0 | 0 | Pin control |
| 0 | 1 | Mixed control |
| 1 | 1 | Serial control |

## THE SWITCH (MUX/DEMUX/UNICAST/BICAST/LOOPBACK)

The mux and demux functions of the AD8158 can be controlled either with the toggle pins or through the register map. The multiplexer path switches received data from Input Port A or Input Port B to Output Port C. The SEL[3:0] pins allow switching lanes independently. The demultiplexer path switches received data from Input Port C to Output Port A, Output Port B, or (if bicast mode is enabled) to both Output Port A and Output Port B.

Table 9. Port Selection and Configuration with All Loopbacks Disabled

| BICAST | SELx | Output <br> Port A | Output <br> Port B | Output <br> Port C |
| :--- | :--- | :--- | :--- | :--- |
| 0 | 0 | Ix_C[3:0] | Idle | Ix_A[3:0] |
| 0 | 1 | Idle | Ix_C[3:0] | Ix_B[3:0] |
| 1 | 0 | Ix_C[3:0] | Ix_C[3:0] | Ix_A[3:0] |
| 1 | 1 | Ix_C[3:0] | Ix_C[3:0] | Ix_B[3:0] |

When the device is in unicast mode, the output lanes on either Port A or Port B are in an idle state. In the idle state, the output tail current is set to 0 , and the P and N sides of the lane are pulled up to the output termination voltage through the on-chip termination resistors. To save power, the unused receiver automatically disables.
The AD8158 supports port-level loopback, illustrated in Figure 36. The loopback control pins override the lane select (SEL[3:0]) and bicast control (BICAST) pin settings at the port level. In serial control mode, Bits [6:4] of Register 0x01 control loopback and are equivalent to asserting Pin LB_A, Pin LB_B, and Pin LB_C. Table 10 summarizes the different loopback configurations.
The loopback feature is useful for system debug, self test, and initialization, allowing system ASICs to compare Tx and Rx data sent over a single bidirectional link. Loopback can also be used to configure the device as a 4 - to 12 -lane receive equalizer or backplane redriver.

Table 10. Switch Connectivity vs. Loopback, BICAST, and Port Select Settings

## AD8158

## RECEIVERS

The AD8158 receivers incorporate $50 \Omega$ on-chip termination, ESD protection, and a multizero equalization function capable of delivering up to 18 dB of boost at 4.25 GHz . The AD8158 can compensate signal degradation at 6.5 Gbps from over 40 inches of FR- 4 backplane trace. The receive path also incorporates a loss-of-signal (LOS) function with user programmable threshold and hysteresis, which squelches the associated transmitter when the midband differential voltage falls below a specified threshold value. Finally, the receivers implement a sign-swapping option (P/N swap), which allows the user to invert the sign of the input signal path and eliminates the need for board-level crossovers in the receive channels.

## Input Structure and Allowed Input Levels

The AD8158 tolerates an input common-mode range (measured with zero differential input) of

$$
V_{E E}+0.6 \mathrm{~V}<V_{I N_{-} C M}<V_{C C}+0.3 \mathrm{~V}
$$

Typical supply configurations include, but are not limited to, those listed in Table 11.

Table 11. Typical Input Supply Configurations

| Configuration | $\mathbf{D V}_{\mathbf{c c}}$ | $\mathbf{V}_{\mathrm{cc}}$ | $\mathbf{V}_{\mathrm{TTI}}$ |
| :--- | :--- | :--- | :--- |
| Low $\mathrm{V}_{\text {TII }}$, AC-Coupled Input | $3.3 \mathrm{~V}-1.8 \mathrm{~V}$ | 1.8 V | 1.6 V |
| Single 1.8 V Supply | $3.3 \mathrm{~V}-1.8 \mathrm{~V}$ | 1.8 V | 1.8 V |
| 3.3 V Core | 3.3 V | 3.3 V | 1.8 V |
| Single 3.3 V Supply | 3.3 V | 3.3 V | 3.3 V |

When dc-coupling with LVDS, CML, or ECL signals, it can be advantageous to operate with split or negative supplies (see the Applications Information section). In these applications, it is necessary to observe the maximum voltage ratings between $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{EE}}$ and generally to select supply voltages for $\mathrm{V}_{\mathrm{TTO}}$ and $\mathrm{V}_{\mathrm{TTI}}$ in the range of $\mathrm{V}_{\mathrm{CC}}$ to $\mathrm{V}_{\mathrm{EE}}$ to avoid activating the ESD protection devices.

Figure 37. Functional Diagram of the AD8158 Receiver

Figure 38. Simplified Receiver Input Structure

## LANE DISABLES

By default, the receivers and transmitters enable in an on-demand fashion according to the state of the SEL[3:0], LB_[A:C], and BICAST pins or to the state of the equivalent registers in serial control mode. Register 0x40, Register 0x80, and Register 0xC0 implement per-lane disables for the receivers and Register 0x48, Register 0x88, and Register 0xC8 implement per-lane transmitter disables. These disables override the default settings. Each bit in the register is named for the lane and function it disables. For example, RXDIS B2 disables the receiver on Lane 2 of Port B while TXDIS C3 disables the Lane 3 transmitter of Port C (see Table 12).

## EQUALIZER SETTINGS

Every input lane offers a low power, asynchronous, programmable receive equalizer for NRZ data up to 6.5 Gbps . The pin control interface makes four levels of receive equalization available: $6 \mathrm{~dB}, 12 \mathrm{~dB}, 15 \mathrm{~dB}$, and 18 dB . Register-based control allows the user 10 equalizer settings within this range. High frequency boost increases monotonically (and approximately linearly) with EQ control setting in $\sim 2 \mathrm{~dB}$ steps.
The four LSBs of Register 0x41, Register 0x81, and Register 0xC1 allow programming of all the equalizers in a port simultaneously (see Table 12). The $0 \times 42,0 x 43,0 x 82,0 x 83,0 x C 2$, and 0 xC 3 registers allow per-lane programming of the equalizers (see Table 23). Be aware that writing to the port-level equalizer registers updates and overwrites per-lane settings.

## LOSS OF SIGNAL (LOS)

The serial control interface allows access to the AD8158 loss of signal features. (LOS is not available in pin control mode.) Each receiver includes a low power, loss-of-signal detector. The loss-of-signal circuit monitors the received data stream and generates a system interrupt when the received signal power falls below a programmed threshold. The default threshold is 25 mV diff, referred to the input pins. The LOS circuit monitors the equalized receive waveform and integrates the rms power of
the equalized waveform over a selectable interval of either 2 ns or 10 ns . The detectors are enabled on a per-port basis with Bit 0 of the RXA/B/C LOS control registers ( $0 \times 51,0 x 91,0 x D 1$ ).
By default, when the receiver detects an LOS event, it squelches its associated transmitter, lowering the output current to submicroamps. This prevents the high gain, wide bandwidth signal path from turning low-level system noise on an undriven input pair into a source of hostile crosstalk at the transmitter. The squelch feature can be disabled with Bit 3 of the global squelch control register ( $0 \times 04$ ).
Register 0x50, Register 0x90, and Register 0xD0 set values for the LOS signal detection threshold for Port A, Port B, and Port C, respectively. The recommended setting is Rx LOS threshold register $=0 \times 10$ with Rx LOS control register $=0 \times 05$. This is an optimum setting that all parts are factory tested to comply with (see Table 1).

## LOS Recommended Settings

Rx LOS threshold register: 0x10
Rx LOS control register: 0x05
Register 0x51, Register 0x91, and Register 0xD1 set the integration interval, LOS gain, and the enable state for the LOS feature for Port A, Port B, and Port C, respectively (see Table 14 through Table 16)

Bit 0, LOS_ENB, enables and disables the LOS detectors. (The default setting is enabled, LOS_ENB = 1).
Bit 1, LOS_GSEL, adjusts the detector gain ( $1=$ high gain, $0=$ low gain). A value of 0 is recommended.

Bit 2, LOS_FILT, adjusts the interval over which incoming data is averaged. LOS_FILT = 0 gives a 2 ns interval and LOS_FILT = 1 sets a 10 ns interval.
Bit 7 through Bit 3 should be set to 0 .

Table 16. Loss-of-Signal Configuration Bits

| Bit(s) | Function | Description | Default |
| :---: | :---: | :---: | :---: |
| THRBIT[5:0] | LOS threshold | Binary coded value between 0 and 31. Covers ranges of 10 mV to 60 mV and 60 mV to 250 mV for LOS_GSEL $=0$ and LOS_GSEL $=1$, respectively. <br> Recommended setting $=0 \times 10$. | $\begin{aligned} & 0 \times 1 \mathrm{C} \\ & \mathrm{~V}_{\text {IN_DC }}<50 \mathrm{mV} \end{aligned}$ |
| LOS_FILT | LOS filter | Loss-of-signal filter. <br> 0 : LOS integrates 2 ns of data. <br> 1: LOS integrates 10 ns of data. | 1 |
| LOS_GSEL | LOS sensitivity | LOS gain select. <br> Recommended setting $=0$. <br> 0 : LOS covers an input range of 60 mV to 250 mV . <br> 1: LOS covers an input range of 10 mV to 60 mV . | 1 |
| LOS_ENB | LOS enable | LOS enable. <br> 0 : LOS function disabled <br> 1: LOS function enabled | 1 |

The LOS_INT pin evaluates a logical OR of all LOS status register bits for all enabled receivers. (LOS status registers are located at $0 \mathrm{x} 45,0 \mathrm{x} 85$, and $0 \mathrm{xC5}$.) The upper four bits in the RXA, RXB, and RXC LOS status registers are sticky while the four LSBs are continuously updated to indicate the instantaneous status of LOS for an enabled receiver. The sticky bits are cleared by writing 0 to the RXA, RXB, and RXC LOS status registers. The LOS_INT pin remains high after an LOS event until all sticky registers are cleared and all active status registers (for example, Bits [3:0]) read 0 .

The LOS_INT pin can be used to generate an interrupt for the system control software. In a standard implementation, when LOS_INT goes high, the system software registers the interrupt and polls the RXA, RXB, and RXC LOS status registers to determine which input lost signal and if the signal has been restored.

## LANE INVERSION: P/N SWAP

The receiver $\mathrm{P} / \mathrm{N}$ swap function is a convenience intended to allow the user to implement the equivalent of a board-level routing crossover in a much smaller area while eliminating vias (impedance discontinuities) that compromise the high frequency integrity of the signal path.

## A Note of Caution

Using this feature to correct an inversion downstream of the receiver may require the user to be aware of the sign of the data when switching connectivity (the mux/demux path). The feature is available on a per-lane setting through Register 0x44, Register 0x84, and Register 0xC4. Setting the bit true flips the sign sense of the P and N inputs for the associated lane. The default setting is 0 (no inversion).

## TRANSMITTERS

The AD8158 transmitter offers programmable pre-emphasis, programmable output levels, output disable, and transmit squelch. The SEL4G pin lets the user lower the transmitter frequency of maximum boost from 3.25 GHz to 2.0 GHz ,
allowing the AD8158 to offer exceptional transmit channel compensation for legacy applications (4.5 Gbps and slower).

## OUTPUT LEVEL PROGRAMMING AND OUTPUT STRUCTURE

The output level of the transmitter of each lane is independently programmable. In pin control mode, a default output amplitude of 800 mV p-p diff ( $\pm 400 \mathrm{mV}$ diff) is delivered (see Table 17). Register-based control allows the user to set the transmitter output levels on a per-port or per-lane basis to four predefined levels. Port-level programming overwrites lane-level configuration. The ALEV, BLEV, and CLEV bits in Register 0x49, Register 0x89, and Register 0 xC 9 , respectively, are used to set the output levels for all transmitters. The A[3:0]OLEV[1:0], B[3:0]OLEV[1:0], and C[3:0]OLEV[1:0] bits in Register 0x4C, Register 0x8C, and Register 0xCC allow per-lane settings (see Table 23).

Table 17. Predefined Output Levels

| [A/B/C]OLEV1 | [A/B/C]OLEV0 | Output Level |
| :--- | :--- | :--- |
| 0 | 0 | $\pm 200 \mathrm{mV}$ diff |
| 0 | 1 | $\pm 300 \mathrm{mV}$ diff |
| 1 | 0 | $\pm 400 \mathrm{mV}$ diff (default) |
| 1 | 1 | $\pm 600 \mathrm{mV}$ diff |

Note that the choice of output level influences the output common-mode level. A 600 mV diff output level with a full PE range requires a supply and output termination voltage of 2.5 V or higher ( $\mathrm{V}_{\text {тто }}, \mathrm{V}_{\mathrm{CC}} \geq 2.5 \mathrm{~V}$ ).

## PRE-EMPHASIS

Transmitter pre-emphasis levels can be set by pin control or through the control registers. Pin control allows two settings of PE, 0 dB , and 6 dB . The control registers provide seven levels of PE. Note that a larger range of boost settings is available for lower output levels.
Pre-emphasis can be programmed per-port or per-lane. Register 0x49, Register 0x89, and Register 0xC9 set all outputs in a port at once. Registers $0 \mathrm{x} 4 \mathrm{~A}, 0 \mathrm{x} 4 \mathrm{~B}, 0 \mathrm{x} 8 \mathrm{~A}, 0 \mathrm{x} 8 \mathrm{~B}, 0 \mathrm{xCA}$, and 0 xCB allow setting PE on a per-lane basis.

Table 18. Lane Inversion Bits

| Address | Bit 7 | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 | Function |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

| 600 | N/A | 1 | 0 | 1 | 83 | 5.26 |
| 600 | N/A | 1 | 1 | 0 | 100 | 6.02 |

## OUTPUT COMPLIANCE, AC vs. DC COUPLING, MINIMUM SUPPLY VOLTAGE, AND THE TX_HEADROOM BIT

In low voltage applications, users must pay careful attention to both the differential and common-mode signal level. The choice of output voltage swing, pre-emphasis setting, supply voltages ( $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\text {тто }}$ ), and output coupling (ac or dc) affect peak and settled single-ended voltage swings and the commonmode shift measured across the output termination resistors. These choices also affect output current and, consequently, power consumption.

Table 20 shows the change in output common-mode ( $\mathrm{dV}_{\text {осм }}=$ $\mathrm{V}_{\mathrm{CC}}-\mathrm{V}_{\text {OCM }}$ ) with output level ( $\mathrm{V}_{\mathrm{OD}}$ ) and pre-emphasis setting. Table 20 also shows the minimum and maximum dc and peak single-ended output levels $\left(V_{L}, V_{H}, V_{L}\right.$ peak, and $V_{H}$ peak, respectively). The single-ended output levels are calculated for $\mathrm{V}_{\text {тто }}$ supplies of 3.3 V and 1.8 V to illustrate practical challenges of reducing the supply voltage. Table 20 shows the voltage margins required for proper transmitter operation. Minimum $\mathrm{V}_{\mathrm{L}}\left(\min \mathrm{V}_{\mathrm{L}}\right)$ is the lowest single-ended voltage allowed given the user's choice of $\mathrm{V}_{\mathrm{CC}}$ voltage.

For output levels greater than 400 mV diff ( 800 mV p-p diff), or when enabling the TX_HEADROOM bit, operating the part from core supply voltage, $\mathrm{V}_{\mathrm{CC}} \geq 2.5 \mathrm{~V}$, is suggested. In this high current case, setting the TX_HEADROOM bit to 1 allows the transmitter an extra 200 mV of output compliance range. Additional transmitter headroom is enabled on a per-port basis through Bits [6:4] in Register 0x05. A value of 0 disables the headroom generating circuitry; a value of 1 enables it.

## Examples

Consider a typical application using pin control mode. In this case, the default output level of 400 mV diff ( 800 mV p-p diff) is selected and the user can choose pre-emphasis settings of 0 dB or 6 dB . Table 19 shows that with pre-emphasis disabled, a dc-coupled transmitter causes a 200 mV common-mode shift across the termination resistors whereas an ac-coupled transmitter causes twice the common-mode shift. Notice that with $V_{c c}$ and $\mathrm{V}_{\text {тто }}$ powered from a 1.8 V supply, the single-ended output voltage swings between 1.8 V and 1.4 V when dc-coupled and between 1.6 V and 1.2 V when ac-coupled. (Note also that $\mathrm{V}_{\mathrm{H}}=$ $\mathrm{V}_{\mathrm{H}}$ peak and $\mathrm{V}_{\mathrm{L}}=\mathrm{V}_{\mathrm{L}}$ peak because transmitter pre-emphasis is disabled.) In both cases, these levels are greater than the minimum $\mathrm{V}_{\mathrm{L}}$ limit of 725 mV , and $\mathrm{V}_{\mathrm{CC}}$ satisfies the minimum $\mathrm{V}_{\mathrm{CC}}$ limit of 1.8 V with the TX_HEADROOM bit set to 0 . Note that setting TX_HEADROOM $=1$ violates the minimum $\mathrm{V}_{\mathrm{CC}}$ limit of 2.5 V .

With a PE setting of 6.02 dB , the ac-coupled transmitter has single-ended swings from 1.4 V to 0.6 V while the dc-coupled transmitter outputs swing between 1.8 V and 1 V . The peak minimum single-ended swing ( $\mathrm{V}_{\mathrm{L}}$ peak) of the ac-coupled transmitter, in this case, exceeds the minimum $\mathrm{V}_{\mathrm{L}}$ limit of 725 mV by 125 mV . While objectionable in theory, in practice, this setting works quite well. The transmitter theoretical peak voltage is rarely achieved in practice because the high frequency characteristic of the pre-emphasis is attenuated at the output pins by the low-pass nature of the PC board environment and the channel. For $6.5 \mathrm{Gbps} \operatorname{PE}(\mathrm{SEL4G}=0)$, a $30 \%$ reduction of overshoot is not unexpected. For an output level of 400 mV diff and a PE setting of 6 dB , the user can calculate a maximum overshoot of 400 mV diff but can measure only a 270 mV overshoot.

Theory (maximum)
V_overshoot_max $=V_{O D} \times(P E[\mathrm{~V} / \mathrm{V}]-1)$
Measured
V_overshoot_measured $=V_{O D} \times(P E[\mathrm{~V} / \mathrm{V}]-1) \times(1-0.3)$
With the pre-emphasis configured for 4.25 Gbps operation (SEL4G $=1$ ), the overshoot can only be reduced $5 \%$ from the theoretic maximum. In this case, the peak minimum voltage limit should be more closely observed.

## AD8158

## SIGNAL LEVELS AND COMMON-MODE SHIFT FOR AC-COUPLED AND DC-COUPLED OUTPUTS

Table 20. Output Voltage Range and Output Common-Mode Shift vs. Output Level and PE Setting

Table 21. Symbol Definitions

| Symbol | Formula | Definition |
| :---: | :---: | :---: |
| Vod | $25 \Omega \times 1 \mathrm{lc}$ | Peak differential output voltage |
| $V_{\text {od }} \mathrm{p}-\mathrm{p}$ | $25 \Omega \times \mathrm{ldC} \times 2=2 \times \mathrm{V}_{\text {OD }}$ | Peak-to-peak differential output voltage |
| $\Delta V_{\text {ocm_dacoloupled }}$ | $25 \Omega \times \mathrm{ITx}^{2} / 2=\mathrm{V}_{\text {odpp }} / 4+(\mathrm{l} / \mathrm{L} / 2 \times 25)$ | Output common-mode shift |
| $\Delta V_{\text {ocm_ac-coupled }}$ | $50 \Omega \times \mathrm{ITx}^{2} / 2=\mathrm{V}_{\text {ODPP }} / 2+(\mathrm{IPE} / 2 \times 50)$ | Output common-mode shift |
| l D | $\mathrm{V}_{\text {od/R }}$ /RERM | Output current that sets output level |
| IPE | N/A | Output current used for PE |
| 1 IT | lde + Ipe | Total transmitter output current |
| $\mathrm{V}_{\mathrm{H}}$ | $\mathrm{V}_{\text {то }}-\Delta \mathrm{V}_{\text {осм }}+\mathrm{V}_{\text {od }} / 2$ | Maximum single-ended output voltage |
| $\mathrm{V}_{\mathrm{L}}$ | $\mathrm{V}_{\text {то }}-\Delta \mathrm{V}_{\text {осм }}-\mathrm{V}_{\text {OD }} / 2$ | Minimum single-ended output voltage |

Figure 40. $V_{H}, V_{L}, V_{\text {OCM }}$

## SQUELCH AND DISABLE

Each transmitter is equipped with disable and squelch controls. Disable is a full power-down state: the transmitter current is reduced to zero and the output pins pull up to $\mathrm{V}_{\text {тто }}$, but there is a delay of approximately $1 \mu \mathrm{~s}$ associated with re-enabling the transmitter. Squelch simply reduces the output current to submicroamp levels, again allowing both output pins to pull up to $\mathrm{V}_{\text {тто }}$ through the output termination resistors. The transmitter recovers from squelch in less than 100 ns .

## SPEED SELECT

The SEL4G pin lets the user lower the transmitter frequency of maximum boost from 3.25 GHz to 2.0 GHz , allowing the AD8158 to offer exceptional transmit channel compensation for legacy applications ( 4.5 Gbps and slower). SEL4G $=1$ lowers the frequency of maximum boost without sacrificing the amount of boost delivered.

## AD8158 POWER CONSUMPTION

There are several sections of the AD8158 that draw varying power depending on the supply voltages, the type of I/O coupling used, and the status of the AD8158 operation. Figure 41 shows a block diagram of these sections. Figure 42 summarizes the power consumption of each section and is a useful guide as the following sections are reviewed.

A power budget calculator is available on the AD 8158 product page at www.analog.com.

Figure 41. AD8158 Power Distribution Block Diagram

## AD8158

The first section is the input termination resistors. The power dissipated in the termination resistors is due to the input differential swing and any common-mode current resulting from dc-coupling the input.
In the next section, the receiver, each input is powered only when it is selected and the disable bits are set to 0 . If a receiver is not selected, it is powered down. Thus, the total number of active inputs affects the total power consumption. Furthermore, the loss-of-signal detection circuits can be disabled independent of the receiver for even greater power savings.
The core of the device performs the multiplexer and demultiplexer switching functions. It draws a fixed quiescent current of 2 mA whenever the AD8158 is powered from $\mathrm{V}_{\mathrm{CC}}$ to $\mathrm{V}_{\mathrm{EE}}$. The switch draws an additional $8 \times 4.6 \mathrm{~mA}$ in normal mux/demux operation and an additional $12 \times 4.6 \mathrm{~mA}$ with all ports in loopback or with bicast selected. The switch core can be disabled to save power.

An output predriver section draws a current, Ipred, that is related to the programmed output current, $\mathrm{I}_{\text {тот. }}$. Table 20 lists values for $\mathrm{I}_{\text {тот }}$ and Ipred for all settings of output level and preemphasis. The predriver current always flows from $\mathrm{V}_{\mathrm{CC}}$ to $\mathrm{V}_{\mathrm{EE}}$. It is treated separately from the output current, which flows from $V_{\text {TTO, }}$, and may not be the same voltage as $V_{\text {CC }}$.
The final section is the outputs. For an individual output, the programmed output current flows through two separate paths. One is the on-chip termination resistor, and the other is the transmission line and the destination termination resistor. The nominal parallel impedance of these two paths is $25 \Omega$. The sum of these two currents flows through the switches and the current source of the AD8158 output circuit and out through $\mathrm{V}_{\mathrm{EE}}$. The power dissipated in the transmission line and the destination resistor is not dissipated in the AD8158 but has to be supplied from the power supply and is a factor in the overall system power. The current in the on-chip termination resistors and the output current source dissipate power in the AD8158 itself.

## OUTPUTS

The output current is set by a combination of output level and pre-emphasis setting (see Table 20). For the two logic switch states, this current flows through an on-chip termination resistor and a parallel path to the destination device and its termination resistor. The power in this parallel path is not dissipated by the AD8158. With pre-emphasis enabled, some current always flows in both the P and N termination resistors.

This pre-emphasis current gives rise to an output commonmode shift, which varies with ac-coupling or dc-coupling and which is calculated for both cases in Table 20.

Perhaps the most direct method for calculating power dissipated in the output is to calculate the power that would be dissipated if all of $\mathrm{I}_{\text {Tot }}$ were to flow on-die from $\mathrm{V}_{\mathrm{TTO}}$ to $\mathrm{V}_{\mathrm{EE}}$ and to subtract from this the power dissipated off-die in the destination device termination resistors and the channel. For this purpose, the destination device and channel can be modeled as $50 \Omega$ load resistors, $\mathrm{R}_{\mathrm{L}}$, in parallel with the AD8158 termination resistors.

## POWER SAVING CONSIDERATIONS

While the AD8158 power consumption is very low compared to similar devices, careful control of its operating conditions can yield further power savings. Significant power reduction can be realized by operating the part at a lower voltage. Compared to 3.3 V operation, a supply voltage of 1.8 V can result in power savings of $\sim 45 \%$. There is no performance penalty when operating at lower voltage.
A second measure is to disable transmitters when they are not being used. This can be done on a static basis if the output is not used or on a dynamic basis if the output does not have a constant stream of traffic. On transmit disable (Register 0x48, Register 0x88, Register 0xC8), both the predriver and output switch currents are disabled. The LOS-activated squelch disables only the output switch current, $\mathrm{I}_{\mathrm{TO}}$. Superior power saving is achieved by using the TX and RX disable registers to turn off an unused lane as opposed to relying on the AD8158 transmit squelch feature.
Because the majority of the power dissipated is in the output stage, some of its flexibility can be used to lower the power consumption. First, the output current and output pre-emphasis settings can be programmed to the smallest amount required to maintain BER performance. If an output circuit always has a short length and the receiver has good sensitivity, then a lower output current can be used.
It is also possible to lower the voltage on $\mathrm{V}_{\text {тто }}$ to lower the power dissipation. The amount that $\mathrm{V}_{\text {тто }}$ can be lowered is dependent on the lowest of all the output's $V_{\text {OL }}$ and $V_{\text {CC. }}$. This is determined by the output that is operating at the highest programmed output current. Table 1 and Table 20 list minimum output levels.

## I ${ }^{2} \mathrm{C}$ CONTROL INTERFACE

## SERIAL INTERFACE GENERAL FUNCTIONALITY

The AD8158 register set is controlled through a 2 -wire $\mathrm{I}^{2} \mathrm{C}$ interface. The AD8158 acts only as an $\mathrm{I}^{2} \mathrm{C}$ slave device. The 7-bit slave address for the AD8158 I2C interface contains the static value b1010 for the upper four bits. The lower three bits are controlled by the input pins I2C_A[2:0].
Therefore, the $\mathrm{I}^{2} \mathrm{C}$ bus in the system needs to include an $\mathrm{I}^{2} \mathrm{C}$ master to configure the AD8158 and other $\mathrm{I}^{2} \mathrm{C}$ devices that may be on the bus. Data transfers are controlled through the use of the two $\mathrm{I}^{2} \mathrm{C}$ wires: the SCL input clock pin and the SDA bidirectional data pin.

The AD8158 $\mathrm{I}^{2} \mathrm{C}$ interface can be run in the standard ( 100 kHz ) and fast ( 400 kHz ) modes. The SDA line only changes value when the SCL pin is low with two exceptions. To indicate the beginning or continuation of a transfer, the SDA pin is driven low while the SCL pin is high, and to indicate the end of a transfer, the SDA line is driven high while the SCL line is high. Therefore, it is important to control the SCL clock to toggle only when the SDA line is stable unless indicating a start, repeated start, or stop condition.

## $I^{2}$ C INTERFACE DATA TRANSFERS: DATA WRITE

To write data to the AD8158 register set, a microcontroller or any other $I^{2} \mathrm{C}$ master needs to send the appropriate control signals to the AD8158 slave device. The following steps need to be taken, where the signals are controlled by the $\mathrm{I}^{2} \mathrm{C}$ master, unless otherwise specified. For a diagram of the procedure, see Figure 43.

1. Send a start condition (while holding the SCL line high, pull the SDA line low).
2. Send the AD8158 part address (seven bits) whose upper four bits are the static value b1010 and whose lower three bits are controlled by the I2C_A [2:0] input pins. This transfer should be MSB first.
3. Send the write indicator bit (0).
4. Wait for the AD8158 to acknowledge the request.
5. Send the register address (eight bits) to which data is to be written. This transfer should be MSB first.
6. Wait for the AD 8158 to acknowledge the request.
7. Send the data (eight bits) to be written to the register whose address was set in Step 5. This transfer should be MSB first.
8. Wait for the AD 8158 to acknowledge the request.

9a. Send a stop condition (while holding the SCL line high, pull the SDA line high) and release control of the bus.
$9 b$. Send a repeated start condition (while holding the SCL line high, pull the SDA line low) and continue with Step 2 in this procedure to perform another write.
9c. Send a repeated start condition (while holding the SCL line high, pull the SDA line low) and continue with Step 2 of the read procedure (in the I2C Interface Data Transfers: Data Read section) to perform a read from another address.
9d. Send a repeated start condition (while holding the SCL line high, pull the SDA line low) and continue with Step 8 of the read procedure (in the I2C Interface Data Transfers: Data Read section) to perform a read from the same address set in Step 5.

In Figure 43, the AD8158 write process is shown. The SCL signal is shown along with a general write operation and a specific example. In this example, the value 0 x 92 is written to Address 0x6D of an AD8158 device with a part address of 0x53. The part address is seven bits wide and is composed of the AD8158 static upper four bits (b1010) and the pin-programmable lower three bits (I2C_A[2:0]). The address pins are set to b011. In Figure 43, the corresponding step number is visible in the circle under the waveform. The SCL line is driven by the $\mathrm{I}^{2} \mathrm{C}$ master and never by the AD8158 slave. As for the SDA line, the data in the shaded polygons is driven by the AD8158, whereas the data in the nonshaded polygons is driven by the $\mathrm{I}^{2} \mathrm{C}$ master. The end phase case shown is that of Step 9A.
It is important to note that the SDA line only changes when the SCL line is low, except for the case of sending a start, stop, or repeated start condition (Step 1 and Step 9 in this case).

## I²C INTERFACE DATA TRANSFERS: DATA READ

To read data from the AD8158 register set, a microcontroller or any other $\mathrm{I}^{2} \mathrm{C}$ master needs to send the appropriate control signals to the AD8158 slave device. The following steps need to be taken, where the signals are controlled by the $\mathrm{I}^{2} \mathrm{C}$ master, unless otherwise specified. For a diagram of the procedure, see Figure 44.

1. Send a start condition (while holding the SCL line high, pull the SDA line low).
2. Send the AD8158 part address (seven bits) whose upper four bits are the static value b1010 and whose lower three bits are controlled by the I2C_A[2:0] input pins. This transfer should be MSB first.
3. Send the write indicator bit (0).
4. Wait for the AD8158 to acknowledge the request.
5. Send the register address (eight bits) from which data is to be read. This transfer should be MSB first. The register address is kept in memory in the AD8158 until the part is reset or the register address is written over with the same procedure (Step 1 to Step 6).
6. Wait for the AD8158 to acknowledge the request.
7. Send a repeated start condition (while holding the SCL line high, pull the SDA line low).
8. Send the AD8158 part address (seven bits) whose upper four bits are the static value b1010 and whose lower three bits are controlled by the I2C_A[2:0] input pins. This transfer should be MSB first.
9. Send the read indicator bit (1).
10. Wait for the AD8158 to acknowledge the request.
11. The AD8158 then serially transfers the data (eight bits) held in the register indicated by the address set in Step 5.
12. Acknowledge the data.

13a. Send a stop condition (while holding the SCL line high, pull the SDA line high) and release control of the bus.
13b. Send a repeated start condition (while holding the SCL line high, pull the SDA line low) and continue with Step 2 of the write procedure (see the I2C Interface Data Transfers: Data Write section) to perform a write.
13c. Send a repeated start condition (while holding the SCL line high, pull the SDA line low) and continue with Step 2 of this procedure to perform a read from another address.
13 d . Send a repeated start condition (while holding the SCL line high, pull the SDA line low) and continue with Step 8 of this procedure to perform a read from the same address.

In Figure 44, the AD8158 read process is shown. The SCL signal is shown along with a general read operation and a specific example. In this example, the value $0 \times 49$ is read from Address $0 \times 6 \mathrm{D}$ of an AD8158 device with a 0x53 part address. The part address is seven bits wide and is composed of the AD8158 static upper four bits (b1010) and the pin-programmable lower three bits (I2C_A[2:0]). The address pins are set to b011. In Figure 44, the corresponding step number is visible in the circle under the waveform. The SCL line is driven by the $\mathrm{I}^{2} \mathrm{C}$ master and never by the AD8158 slave. As for the SDA line, the data in the shaded polygons is driven by the AD8158, whereas the data in the nonshaded polygons is driven by the $\mathrm{I}^{2} \mathrm{C}$ master. The end phase case shown is that of Step 13A.

It is important to note that the SDA line only changes when the SCL line is low, except for the case of sending a start, stop, or repeated start condition, as in Step 1, Step 7, and Step 13. In Figure 44, A is the same as ACK. Equally, Sr represents a repeated start where the SDA line is brought high before SCL is raised. SDA is then dropped while SCL is still high.

Figure 44. $1^{2} \mathrm{C}$ Read Diagram

## APPLICATIONS INFORMATION

## SUPPLY SEQUENCING

Ideally, all power supplies should be brought up to the appropriate levels simultaneously (power supply requirements are set by the supply limits in Table 1 and the absolute maximum ratings listed in Table 3). In the event that the power supplies to the AD8158 are brought up separately, the supply power-up sequence is as follows: $\mathrm{DV}_{\mathrm{CC}}$ powered first, followed by $\mathrm{V}_{\mathrm{CC}}$, and lastly $\mathrm{V}_{\text {тті }}$ and $\mathrm{V}_{\text {тто }}$. The power-down sequence is reversed with $\mathrm{V}_{\text {тті }}$ and $V_{\text {тто }}$ being powered off first.
$\mathrm{V}_{\text {тті }}$ and $\mathrm{V}_{\text {тто }}$ contain ESD protection diodes to the $\mathrm{V}_{\text {CC }}$ power domain (see Figure 38 and Figure 39). To avoid a sustained high current condition in these devices (Isustained $<100 \mathrm{~mA}$ ), the $\mathrm{V}_{\text {TTI }}$ and $\mathrm{V}_{\text {Tто }}$ supplies should be powered on after $\mathrm{V}_{\text {CC }}$ and should be powered off before $V_{c c}$.

If the system power supplies have a high impedance in the powered off state, then supply sequencing is not required provided the following limits are observed:

- Peak current from $\mathrm{V}_{\text {тті }}$ or $\mathrm{V}_{\text {тто }}$ to $\mathrm{V}_{\mathrm{CC}}<200 \mathrm{~mA}$
- Sustained current from $\mathrm{V}_{\text {Tті }}$ or $\mathrm{V}_{\text {TTo }}$ to $\mathrm{V}_{\mathrm{CC}}<100 \mathrm{~mA}$

## SINGLE SUPPLY vs. MULTIPLE SUPPLY OPERATION

The AD8158 supports a flexible supply voltage of 1.8 V to 3.3 V . For some dc-coupled links, 1.2 V or ground-referenced signaling may be desired. In these cases, the AD8158 can be run with a split supply configuration.

Table 22. Alternate Supply Configuration Examples

| Signal Level | $\mathbf{V}_{\mathrm{CC}}, \mathbf{V}_{\mathrm{TTI}}, \mathbf{V}_{\mathrm{TTO}}$ | $\mathbf{V}_{\mathrm{EE}}$ |
| :--- | :--- | :--- |
| $1.2 \mathrm{~V} C M L$ | 1.2 V | $-2.1 \mathrm{~V} \leq \mathrm{V}_{\mathrm{EE}} \leq-0.6 \mathrm{~V}$ |
| $\mathrm{GND}-400 \mathrm{mV}$ diff | GND | $-3.3 \mathrm{~V} \leq \mathrm{V}_{\mathrm{EE}} \leq+1.8 \mathrm{~V}$ |

The AD8158 control signals are always referenced between $D V_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{EE}}$ and, when using a split supply configuration, logic level-shift circuits should be used. The evaluation board design shows the use of the Analog Devices, Inc., ADUM1250 $I^{2} \mathrm{C}$ isolator and a level shifter to level-shift the SCL and SDA signals.

## Evaluation of DC-Coupled Links

When evaluating the AD8158 dc-coupled, remember that most lab equipment is ground referenced while the AD8158 high speed I/O are connected by $50 \Omega$ on-die termination resistors to $\mathrm{V}_{\text {тті }}$ and $\mathrm{V}_{\text {тто }}$. To interface the AD8158 to ground-referenced, high speed instrumentation (for example, the $50 \Omega$ inputs of a high speed oscilloscope), it is necessary to level-shift the outputs by either using a dc-blocking network or by powering the AD8158 between ground and a negative supply.
For example, to evaluate 1.8 V dc-coupled transmitter performance with a $50 \Omega$ ground-referenced oscilloscope, use the following supply configuration:

$$
\begin{aligned}
& V_{C C}=V_{T T O}=V_{T T I}=\text { Ground } \\
& V_{E E}=-1.8 \mathrm{~V} \\
& \text { Ground }<D V C C<1.5 \mathrm{~V}
\end{aligned}
$$

[^2]NOTES

## AD8158

## NOTES

[^0]:    ${ }^{1}$ Logic level of control pins referred to $\mathrm{DV}_{c c}$.
    ${ }^{2}$ EQ control pins (EQ_A0, EQ_A1, EQ_B0, EQ_B1,EQ_C0,EQ_C1) require $5 \mathrm{k} \Omega$ in series when $D V_{c c}>\mathrm{V}_{\mathrm{cc}}$.

[^1]:    ${ }^{1}$ Per-lane registers.

[^2]:    ${ }^{1} Z=$ RoHS Compliant Part．
