

FEATURES

- Compresses/expands 64kbps PCM voice to/from either 32kbps, 24kbps, or 16kbps
- Dual fully independent channel architecture; device can be programmed to perform either:
 - two expansions
 - two compressions
 - one expansion and one compression
- Interconnects directly to combo-codec devices
- Input to output delay is less than 375µs
- Simple serial port used to configure the device
- On-board time-slot assigner-circuit (TSAC) function allows data to be input/output at various time slots
- Supports Channel Associated Signaling
- Each channel can be independently idled or placed into bypass
- Available hardware mode requires no host processor; ideal for voice storage applications
- Single +5V supply; low-power CMOS technology
- Available in 28-pin PLCC
- 3V operation version is available (DS2165QL)

PIN ASSIGNMENT (Top View)

DESCRIPTION

The DS2165Q ADPCM processor chip is a dedicated digital-signal-processing (DSP) chip that has been optimized to perform adaptive-differential pulse-code modulation (ADPCM) speech compression at three different rates. The chip can be programmed to compress (expand) 64kbps voice data down to (up from) either 32kbps, 24kbps, or 16kbps. The compression to 32kbps follows the algorithm specified by CCITT Recommendation G.721 (July 1986) and ANSI document T1.301 (April 1987). The compression to 24kbps follows ANSI document T1.303. The compression to 16kbps follows a proprietary algorithm developed by Dallas Semiconductor. The DS2165Q can switch compression algorithms on-the-fly. This allows the user to make maximum use of the available bandwidth on a dynamic basis.

Note: Some revisions of this device may incorporate deviations from published specifications known as errata. Multiple revisions of any device may be simultaneously available through various sales channels. For information about device errata, click here: <http://www.maxim-ic.com/errata>.

OVERVIEW

The DS2165Q contains three major functional blocks: a high performance (10 MIPS) DSP engine, two independent PCM interfaces (X and Y) that connect directly to serial time-division-multiplexed (TDM) backplanes, and a serial port that can configure the device on-the-fly by an external controller. A 10MHz master clock is required by the DSP engine. The DS2165Q can be configured to perform either two expansions, two compressions, or one expansion and one compression. The PCM/ADPCM data interfaces support data rates from 256kHz to 4.096MHz. Typically, the PCM data rates are 1.544MHz for μ -law and 2.048MHz for A-law. Each channel on the device samples the serial input PCM or ADPCM bit stream during a user-programmed input time slot, processes the data and outputs the result during a user-programmed output time slot.

Each PCM interface has a control register that specifies functional characteristics (compress, expand, bypass, and idle), data format (μ -law or A-law), and algorithm reset control. With the SPS pin strapped high, the software mode is enabled and the serial port can be used to configure the device. In this mode, a novel addressing scheme allows multiple devices to share a common 3-wire control bus, simplifying system-level interconnect.

With SPS low, the hardware mode is enabled. This mode disables the serial port and maps certain control register bits to some of the address and serial port pins. Under the hardware mode, no external host controller is required and all PCM/ADPCM input and output time slots default to time slot 0.

HARDWARE RESET

$\overline{\text{RST}}$ allows the user to reset both channel algorithms and the contents of the internal registers. This pin must be held low for at least 1ms on system power-up after the master clock is stable to ensure that the device has initialized properly. $\overline{\text{RST}}$ should also be asserted when changing to or from the hardware mode. $\overline{\text{RST}}$ clears all bits of the control register for both channels except the IPD bits; the IPD bits for both channels are set to 1.

SOFTWARE MODE

Connecting SPS high enables the software mode. In this mode, an external host controller writes configuration data to the DS2165Q by the serial port through inputs SCLK, SDI, and $\overline{\text{CS}}$ (Figure 2). Each write to the DS2165Q is either a 2-byte write or a 4-byte write. A 2-byte write consists of the address/command byte (ACB), followed by a byte to configure the control register (CR) for either the X or Y channel. The 4-byte write consists of the ACB, followed by a byte to configure the CR, and then 1 byte to set the input time slot and another byte to set the output time slot.

ADDRESS/COMMAND BYTE

In the software mode, the address/command byte is the first byte written to the serial port; it identifies which of the 64 possible ADPCM processors sharing the port wiring is to be updated. Address data must match that at inputs A0 to A5. If no match occurs, the device ignores the following configuration data. If an address match occurs, the next 3 bytes written are accepted as control, input and output time slot data. Bit ACB.6 determines which side (X or Y) of the device is to be updated. The PCM and ADPCM outputs are tri-stated during register updates.

CONTROL REGISTER

The control register establishes idle, algorithm reset, bypass, data format, and channel coding for the selected channel.

The X-side and Y-side PCM interfaces can be independently disabled (output tri-stated) by IPD. When IPD is set for both channels, the device enters a low-power standby mode. In this mode, the serial port must not be operated faster than 39kHz.

ALRST resets the algorithm coefficients for the selected channel to their initial values. ALRST is cleared by the device when the algorithm reset is complete.

Table 1. PIN DESCRIPTION

| PIN | SYMBOL | TYPE | FUNCTION |
|------------------------------|----------------------------------|------|---|
| 2 | $\overline{\text{RST}}$ | I | Reset. A high-low-high transition resets the algorithm. The device should be reset on power-up and when changing to or from the hardware mode. |
| 3 4 | TM0 TM1 | I | Test Modes 0 and 1. Connect to V_{SS} for normal operation. |
| 6 7 8 9 10 11 | A0 A1 A2 A3 A4 A5 | I | Address Select. A0 = LSB, A5 = MSB. Must match address/command word to enable the serial port. |
| 12 | SPS | I | Serial Port Select. Connect to V_{DD} to select the serial port; connect to V_{SS} to select the hardware mode. |
| 13 | MCLK | I | Master Clock. 10MHz clock for the ADPCM processing engine; may be asynchronous to SCLK, CLKX, and CLKY. |
| 14 | VSS | — | Signal Ground. 0V |
| 16 | XIN | I | X Data In. Sampled on falling edge of CLKX during selected time slots. |
| 17 | CLKX | I | X Data Clock. Data clock for the X-side PCM interface; must be synchronous with FSX. |
| 18 | FSX | I | X Frame Sync. 8kHz frame sync for the X-side PCM interface. |
| 20 | XOUT | O | X Data Output. Updated on rising edge of CLKX during selected time slots. |
| 21 | SCLK | I | Serial Data Clock. Used to write to the serial port registers. |
| 22 | SDI | I | Serial Data In. Data for on-board control registers; sampled on the rising edge of SCLK. LSB sent first. |
| 23 | $\overline{\text{CS}}$ | I | Chip Select. Must be low to write to the serial port. |
| 24 | YOUT | O | Y Data Output. Updated on rising edge of CLKY during selected time slots. |
| 25 | FSY | I | Y Frame Sync. 8kHz frame sync for the Y-side PCM interface. |
| 26 | CLKY | I | Y Data Clock. Data clock for the Y-side PCM interface; must be synchronous with FSY. |
| 27 | YIN | I | Y Data In. Sampled on falling edge of CLKY during selected time slots. |
| 28 | VDD | — | Positive Supply. 5.0V (3.0V for DS2165QL) |

Figure 1. BLOCK DIAGRAM

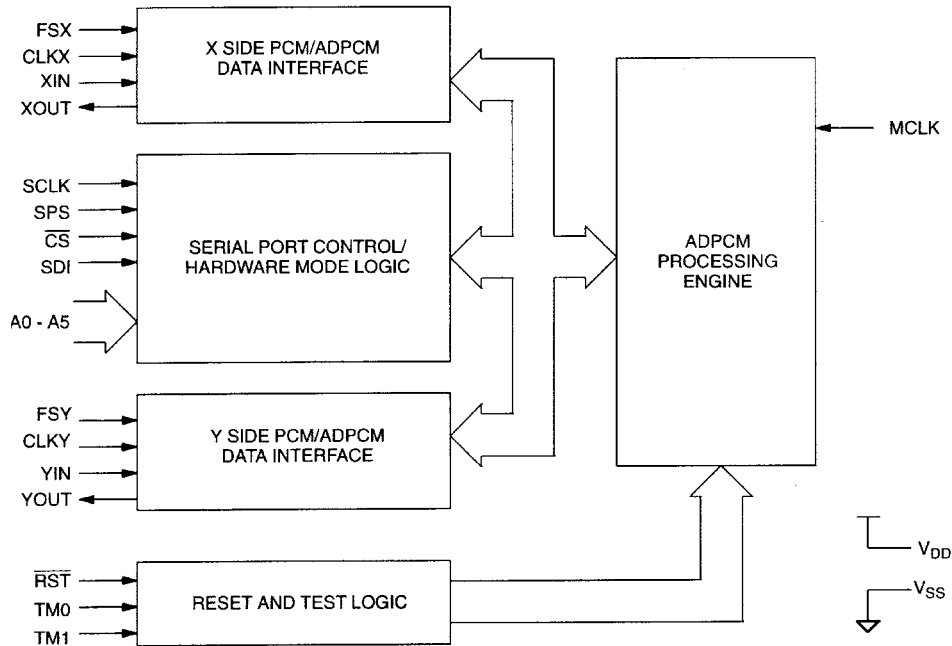

Figure 2. SERIAL PORT WRITE

Note: A 2-byte write is shown.

The bypass feature is enabled when \overline{BYP} is set and \overline{IPD} is cleared. During bypass, no expansion or compression occurs. Bypass operates on byte-wide (8 bits) slots when $\overline{CP/EX}$ is set and on nibble-wide (4 bits) slots when $\overline{CP/EX}$ is cleared.

A-law ($\overline{U/A} = 0$) and μ -law ($\overline{U/A} = 1$) PCM coding is independently selected for the X and Y channels by CR.2. If \overline{BYP} and \overline{IPD} are cleared, then $\overline{CP/EX}$ determines if the input data is to be compressed or expanded.

TIME SLOT ASSIGNMENT/ORGANIZATION

On-board counters establish when PCM and ADPCM I/O occur. The counters are programmed by the time slot registers. Time slot size (number of bits wide) is determined by the state of CP/\overline{EX} . The number of time slots available is determined by the state of both CP/\overline{EX} and U/\overline{A} (Figures 7 through 10). For example, if the X channel is set to compress ($CP/\overline{EX} = 1$) and it is set to expect μ -law data ($U/\overline{A} = 1$), then the input port (XIN) is set up for 32 8-bit time slots and the output port (XOUT) is set up for 64 4-bit time slots. The time slot organization is not dependent on which algorithm has been selected.

Note: Time slots are counted from the frame sync signal starting at the first rising edge of either CLKX or CLKY after the frame sync.

Figure 8. μ -LAW ADPCM INTERFACE

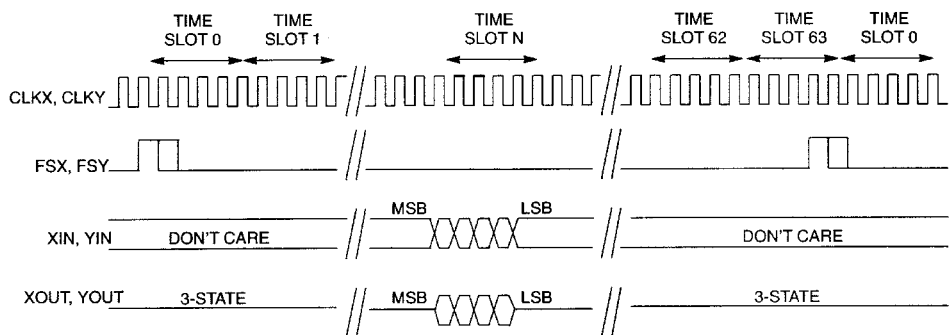

Figure 9. A-LAW PCM INTERFACE

Figure 10. A-LAW ADPCM INTERFACE

HARDWARE MODE

The hardware mode is intended for applications that do not have an external controller available or do not require the extended features offered by the serial port. Connecting the SPS pin to V_{SS} disables the serial port, clears all internal register bits, and maps the IPD, U/\overline{A} , and CP/\overline{EX} bits for both channels to external bits (Table 3). In the hardware mode, both the input and output time slots default to time slot 0.

Table 3. HARDWARE MODE

| PIN | | REGISTER LOCATION | FUNCTION |
|-----|-----------------|-----------------------------------|---|
| # | NAME | | |
| 6 | A0 | CP/\overline{EX} (Channel X) | Channel X Coding Configuration 0 = Expand 1 = Compress |
| 7 | A1 | AS0/AS1/AS2 (Channel X and Y) | Algorithm Select (Table 4) |
| 8 | A2 | U/\overline{A} (Channel X) | Channel X Data Format 0 = A-law 1 = μ -law |
| 9 | A3 | CP/\overline{EX} (Channel Y) | Channel Y Coding Configuration 0 = Expand 1 = Compress |
| 10 | A4 | AS0/AS1/AS2 (Channel X and Y) | Algorithm Select (Table 4) |
| 11 | A5 | U/\overline{A} (Channel Y) | Channel Y Data Format 0 = A-law 1 = μ -law |
| 22 | SDI | IPD (Channel Y) | Channel Y Idle Select 0 = Channel Active 1 = Channel Idle |
| 23 | \overline{CS} | IPD (Channel X) | Channel X Idle Select 0 = Channel Active 1 = Channel Idle |

NOTES:

- 1) SCLK must be connected to V_{SS} when the hardware mode is selected.
- 2) When both channels are idled, power consumption is significantly reduced.
- 3) The NIL powers up within 800ms after either channel is returned to active from an idle state.

Table 4. ALGORITHM SELECT FOR HARDWARE MODE

| ALGORITHM | CONFIGURATION OF A1 AND A4 |
|-----------------------|---|
| 64kbps to/from 32kbps | Connect both A1 and A4 to V _{SS} . |
| 64kbps to/from 24kbps | Hold A1 and A4 low during a hardware reset; take both A1 and A4 high after the $\overline{\text{RST}}$ pin has returned high (allow 3 μ s after $\overline{\text{RST}}$ returns high before taking A1 and A4 high). |
| 64kbps to/from 16kbps | Connect both A1 and A4 to V _{DD} . |

PCM AND ADPCM INPUT/OUTPUT

Since the organization of the input and output time slots on the DS2165Q does not depend on the algorithm selected, it always assumes that PCM input and output are in 8-bit bytes and that ADPCM input and output are in 4-bit bytes. Figure 12 demonstrates how the DS2165Q handles the I/O for the three different algorithms. In the figure, it is assumed that channel X is in the compression mode ($CP/\overline{EX} = 1$) and channel Y is in the expansion mode ($CP/\overline{EX} = 0$). Also, it is assumed that both the input and output time slots for both channels are set to 0.

Figure 12. PCM AND ADPCM I/O EXAMPLE

Note 1: The bit after the LSB in the 24kbps ADPCM output is only a 1 when the DS2165Q is operated in the software mode and is programmed to perform 24kbps compression; in all other configurations, it is a 0.

TIME SLOT RESTRICTIONS

Under certain conditions, the DS2165Q does contain some restrictions on the output time slots that are available. These restrictions are covered in detail in a separate application note. No restrictions occur if the DS2165Q is operated in the hardware mode.

INPUT TO OUTPUT DELAY

With all three compressions algorithms, the total delay, from the time the PCM data sample is captured by the DS2165Q to the time it is output, is always less than 375 μ s. The exact delay is determined by the input and output time slots selected for each channel.

CHANNEL ASSOCIATED SIGNALING

The DS2165Q supports Channel Associated Signaling (CAS) through its ability to automatically change from the 32kbps compression algorithm to the 24kbps algorithm. If the DS2165Q is configured to perform the 32kbps algorithm, then in both the hardware and software mode it senses the frame sync inputs (FSX and FSY) for a double-wide frame-sync pulse. Whenever the DS2165Q receives a double-wide pulse, it automatically switches from the 32kbps algorithm to the 24kbps algorithm. Switching to the 24kbps algorithm allows the user to insert signaling data into the LSB bit position of the ADPCM output because this bit does not contain any useful speech information.

ON-THE-FLY ALGORITHM SELECTION

In the software mode, the user can switch between the three available algorithms on-the-fly. That is, the DS2165Q does not need to be reset or stopped to make the change from one algorithm to another. The DS2165Q reads the control register before it starts to process each PCM or ADPCM sample. If the user wishes to switch algorithms, then the control register must be updated by the serial port before the first input sample to be processed with the new algorithm arrives at either XIN or YIN. The PCM and ADPCM outputs tri-state during register updates.
