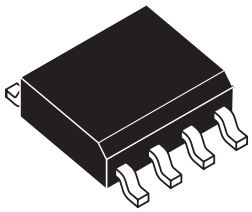
LCDP1521

DUAL LINE PROGRAMMABLE TRANSIENT VOLTAGE SUPPRESSOR FOR SLIC PROTECTION

A.S.D.™

FEATURES

- Dual line programmable transient voltage suppressor
- Wide negative firing voltage range: V_{MGL} = -150 V max.
- Low dynamic switching voltages: V_{FP} and V_{DGL}
- Low gate triggering current: I_{GT} = 5 mA max
- Peak pulse current: I_{PP} = 15 A (10/1000 µs)
- Holding current: I_H = 150 mA min



SO-8

DESCRIPTION

This device has been especially designed to protect 2 new high voltage, as well as classical SLICs, against transient overvoltages.

Positive overvoltages are clamped by 2 diodes. Negative surges are suppressed by 2 thyristors, their breakdown voltage being referenced to $-V_{BAT}$ through the gate.

This component presents a very low gate triggering current (I_{GT}) in order to reduce the current consumption on printed circuit board during the firing phase.

BENEFITS

Trisils are not subject to ageing and provide a fail safe mode in short circuit for a better protection. Trisils are used to help equipment to meet various standards such as UL1950, IEC950 / CSA C22.2, UL1459 and FCC part68. Trisils have UL94 V0 resin approved (Trisils are UL497B approved (file: E136224)).

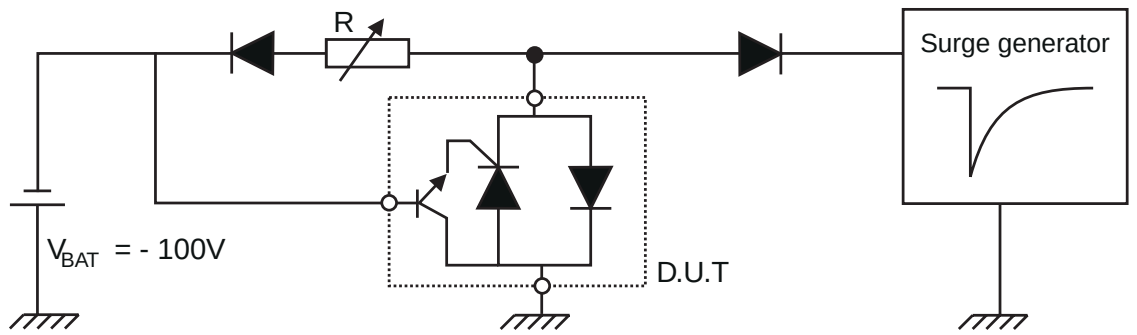
FUNCTIONAL HOLDING CURRENT (I_H) TEST CIRCUIT : GO-NO GO TEST



This is a GO-NO GO test which allows to confirm the holding current (I_H) level in a functional test circuit.

TEST PROCEDURE :

- Adjust the current level at the I_H value by short circuiting the D.U.T.
- Fire the D.U.T. with a surge current : I_{PP} = 10A, 10/1000µs.
- The D.U.T. will come back to the off-state within a duration of 50ms max.

TECHNICAL INFORMATION

Fig. A1: LCDP1521 concept behavior.

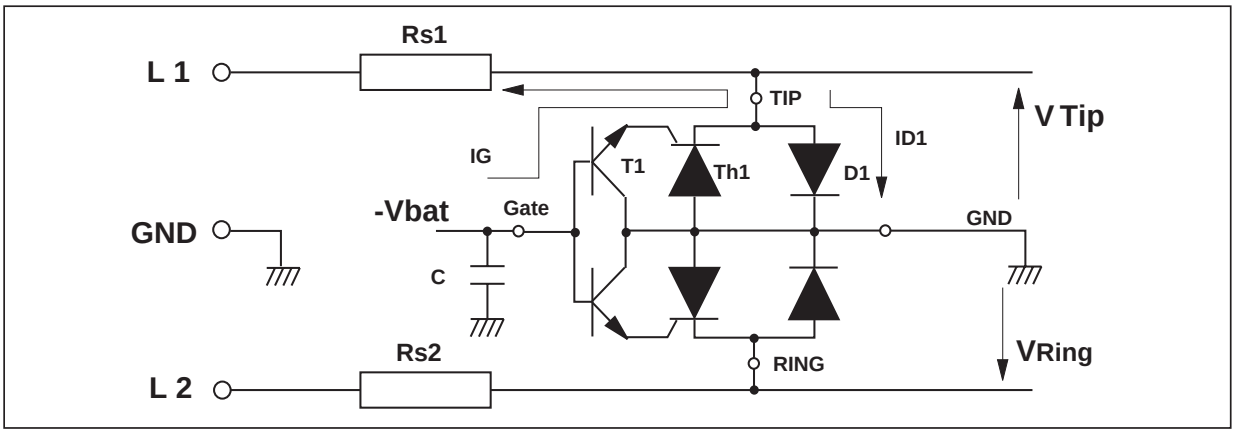

Figure A1 shows the classical protection circuit using the LCDP1521 crowbar concept. This topology has been developed to protect the new high voltage SLICs. It allows to program the negative firing threshold while the positive clamping value is fixed at GND.

When a negative surge occurs on one wire (L1 for example), a current IG flows through the base of the transistor T1 and then injects a current in the gate of the thyristor Th1. Th1 fires and all the surge current flows through the ground. After the surge when the current flowing through Th1 becomes less negative than the holding current I_H, then Th1 switches off.

When a positive surge occurs on one wire (L1 for example), the diode D1 conducts and the surge current flows through the ground.

The capacitor C is used to speed up the crowbar structure firing during the fast surge edges.
This allows to minimize the dynamical breakover voltage at the SLIC Tip and Ring inputs during fast strikes. Note that this capacitor is generally present around the SLIC - Vbat pin.
So to be efficient it has to be as close as possible from the LCDP1521 Gate pin and from the reference ground track (or plan). The optimized value for C is 220nF.

The series resitors Rs1 and Rs2 designed in figure A1 represent the fuse resistors or the PTC which are mandatory to withstand the power contact or the power induction tests imposed by the various country standards. Taking into account this fact the actual lightning surge current flowing through the LCDP is equal to:

$$I_{surge} = V_{surge} / (Rg + Rs)$$

With V surge = peak surge voltage imposed by the standard.
Rg = series resistor of the surge generator
Rs = series resistor of the line card (equivalent to PTC + R on Fig. A2)

e.g. For a line card with 60Ω of series resistors which has to be qualified under GR1089 Core 1000V 10/1000µs surge, the actual current through the LCDP1521 is equal to:

$$I_{surge} = 1000 / (10 + 60) = \mathbf{14A}$$

The LCDP1521 is particularly optimized for the new telecom applications such as the fiber in the loop, the WLL, the remote central office. In this case, the operating voltages are smaller than in the classical system. This makes the high voltage SLICs particularly suitable. The schematics of figure A2 gives the most frequent topology used for these applications.
