

M66312P/FP

8-BIT LED DRIVER WITH SHIFTRREGISTER AND LATCHED 3-STATE OUTPUTS

DESCRIPTION

M66312 is a LED array driver having a 8-bit serial input and parallel output shiftrregister function with 3-state output latch.

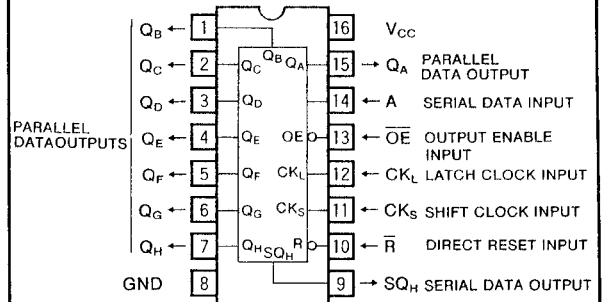

This product guarantees the output electric current of 16mA which is sufficient for LED drive, capable of flowing 8 bits continuously at the same time, and use either of cathode common LED and anode common LED.

In addition, as this product has been designed in complete CMOS, power consumption can be greatly reduced when compared with conventional BIPOLAR or Bi-CMOS products.

FEATURES

- High output current $I_{OL}=16\text{mA}$, $I_{OH}=-16\text{mA}$
- High speed (clock frequency) : 30MHz (typ)
($C_L=50\text{pF}$, $V_{CC}=5\text{V}$)
- Low power dissipation : 20μW/package (max)
($V_{CC}=5\text{V}$, $T_a=25^\circ\text{C}$, quiescent state)
- 3-state output (except serial data output)
- Wide operating temperature range : $T_a=-40\sim+85^\circ\text{C}$

FUNCTIONAL DESCRIPTION

As M66312 uses silicon gate CMOS process, it realizes high-speed and high-output currents sufficient for LED drive while maintaining low power consumption and allowance for high noises.

Each bit of a shiftrregister consists of two flip-flops having independent clocks for shifting and latching.

As for clock input, shift clock input CK_S and latch clock input CK_L are independent from each other, shift and latch operations being made when "L" changes to "H".

Serial data input A is the data input of the first-step shiftrregister and the signal of A shifts shiting registers one by one when a pulse is impressed to CK_S. When A is "H", the signal of "H" shifts. When A is "L", the signal of "L" shifts.

When the pulse is impressed to CK_L, the contents of the

shifting register at that time are stored in a latching register, and they appear in the output from Q_A through Q_H are 3-state outputs.

To extend the number of bits, serial data output SQ_H is used to output the 8-bit of the shift register.

By connecting CKs and CK_L, the shift register state delayed by 1 clock cycle is output at Q_A through Q_H.

When reset input \bar{R} is low, shift register and SQ_H will be reset. To reset Q_A through Q_H to low-level, CK_L must be changed from low-level to high-level after the shift register is reset by \bar{R} .

When output-enable input \overline{OE} is high, Q_A through Q_H will become high impedance state, but SQ_H is not changed. Even if \overline{OE} is changed, shift operation is not affected.
