

### FEATURES

- Fault Protected 16-Channel 12-Bit A/D Converter with Sample & Hold, Reference, Clock and 3-state Outputs
- Fast Conversion, less than 15 $\mu$ S
- Microprocessor Bus Interface
- 2's Complement Data Output
- Parallel or Serial Data Output Modes
- 65 ns Bus Access Time
- Remote Analog Ground Sensing
- Overvoltage Protected Input ( $\pm 50$  V over the Supply Voltages)
- Precision Reference for Long Term Stability and Low Gain T.C.
- Guaranteed Linearity Over Temperature
- Guaranteed Performance at +12/-5 V,  $\pm 12$  &  $\pm 15$  V
- Low Power: 110 mW typ. (7 mW per Channel typ.)
- 32 Channel Version: MP3274

### GENERAL DESCRIPTION

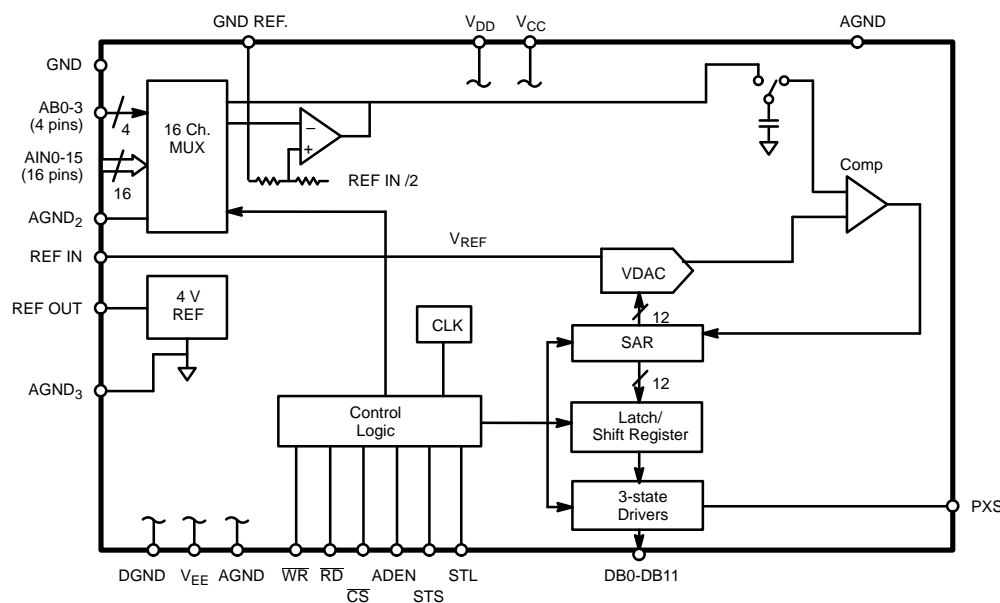

The MP3276 is a complete 16-channel, 12-bit Data Acquisition Subsystem with 3-state output buffers for direct interfacing to 16-bit microprocessor buses. Implemented using an advanced BiCMOS process, the converter combines a 16-channel passive overvoltage protected multiplexer instrumentation amp, a sample & hold, a SAR, a 12-bit decoded D/A, a comparator, a precision reference and the control logic to achieve an accurate repeated conversion in less than 15 $\mu$ s, and a mux/instrumentation amp settling period of less than 10 $\mu$ s.

A unique input design provides input overvoltage protection to  $\pm 50$  V over the supply voltages. The circuit design can allow

for an overvoltage condition on unselected channels without disrupting the measured channel or operation of the MP3276! The internal 4 V reference has sufficient output current to provide other system reference needs. Precision thin film scaling and offset resistors are laser trimmed to provide for less than 2 LSB INL for  $\pm 10$  V inputs on all channels.

In addition, the MP3276 will output either full scale (0111 ....) for overrange and - full scale (1000....) for underrange conditions. This greatly simplifies microprocessor software development.

### NOTES

- 1 Tester measures code transitions by dithering the voltage of the analog input ( $V_{IN}$ ). The difference between the measured and the ideal code width is the DNL error. The INL error is the maximum distance (in LSBs) from the best fit line to any transition voltage Guaranteed. Not tested.
- 2 All channel input pins and ground reference pin have protection which becomes active above  $\pm 60\text{ V}$ .
- 3 All digital inputs have diodes to  $V_{DD}$  and AGND. Input DC currents will not exceed specified limits for any input voltage between GND and  $V_{DD}$ .
- 4 Refin should not vary from Refout by more than  $\pm 10\%$  of the nominal value of Refout.

Specifications are subject to change without notice

### ABSOLUTE MAXIMUM RATINGS ( $T_A = +25^\circ\text{C}$ unless otherwise noted)<sup>1, 2</sup>

$V_{CC}$ to DGND	0 to +16.5 V	REF OUT	Indefinite short to DGND, Momentary short to $V_{CC}$
$V_{EE}$ to DGND	0 to -16.5 V	Maximum Junction Temperature	150°C
$V_{DD}$ to DGND	0 to +7 V	Package Power Dissipation Rating to 75°C	
AGND to DGND	$\pm 1\text{ V}$	PGA, PLCC	1800 mW
Digital Inputs/Outputs to DGND	-0.5 V to $V_{LOGIC} + 0.5\text{ V}$	Derates above 75°C	25 mW/°C
Analog Inputs ( $A_{IN0} - A_{IN31}$ , GND REF) to AGND	$\pm 60\text{ V}$	Lead Temperature, Soldering	300°C, 10 Sec
		Storage Temperature (Ceramic)	-65°C to +150°C

### NOTES:

- 1 Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation at or above this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.
- 2 Any input pin which can see a value outside the absolute maximum ratings should be protected by Schottky diode clamps (HP5082-2835) from input pin to the supplies. All logic inputs have protection diodes which will protect the device from short transients outside the supplies of less than 100mA for less than 100 $\mu\text{s}$ .

## PRODUCT INFORMATION

### Basic Description

The MP3276 is a fault protected data acquisition subsystem available in monolithic form. This product contains all of the circuitry necessary to acquire 16 channels of quasi differential or single-ended analog signals at  $\pm 10$  V input range and 15kHz bandwidth. Connections to power, the analog input signals and the digital system are all that is required. The MP3276's input circuitry is protected against active input signals present with the MP3276 power off. This is also the case for any channel exceed-

ing the MP3276 analog input dynamic range without interfering with the channel being digitized. The channel address and channel conversion can be managed in two ways: random channel conversion or same channel conversion. Circuitry on the chip adds a MUX/instrumentation amp settling (STL) delay of 10 $\mu$ s max, when a new channel is selected (ADEN = 1). Conversion start is initiated without delay for the single-channel case (ADEN = 0). Data is available in either parallel or serial format.

### TIMING

#### Control and Timing Considerations – Parallel Mode (PXS = 1)

The MP3276 can be operated in the stand-alone mode, with one line for control and everything else hard-wired; or under microprocessor control, where changes can be made dynamically. There are 4 control lines: ADEN,  $\overline{CS}$ ,  $\overline{WR}$ , and  $\overline{RD}$  with their functions described in *Table 1*.

PXS is the control pin for formatting data for serial or parallel control.

$\overline{CS}$	$\overline{WR}$	$\overline{RD}$	ADEN	Data	STL	STS	Comments
<b>ADC Channel Select and Start Convert (See Figure 1. and Table 2.)</b>							
1	X	X	X	—	0	0	No operation
0	$\downarrow$	1	0	Hi-Z	0	0	No operation if ADEN = 0
0	$\downarrow$	1	1	Hi-Z	$\uparrow$	0	Input MUX channel selected, STL set on $\overline{WR}$ falling edge
0	0	1	X	Hi-Z	1	0	MUX select disabled
0	$\uparrow$	1	X	Hi-Z	0	$\uparrow$	Start convert on $\overline{WR}$ rising edge
0	1	1	X	Hi-Z	$\downarrow$	$\uparrow$	Start convert on STL falling edge
0	1	1	X	Hi-Z	0	$\downarrow$	STS goes low at end of conversion
<b>Read ADC Data – Parallel Output Mode (PXS = 1) (See Figure 2. and Table 3.)</b>							
0	1	$\downarrow$	X	—	0	0	Data outputs enabled
0	X	0	X	ADC	0	0	Data from previous conversion on data bus
0	X	$\uparrow$	X	Hi-Z	0	0	Data outputs disabled
0	1	X	X	Hi-Z	0	1	Data/ $\overline{RD}$ disabled while STS high
0	X	0	X	Last ADC	1	0	Data from last conversion on data bus
0	$\overline{\square}$	0	0	Hi-Z	0	$\uparrow$	STL, MUX select disabled with ADEN = 0, data outputs disabled on STS rising edge
0	$\overline{\square}$	0	X	ADC	0	$\downarrow$	New data appears on data bus on falling edge of STS

Note 1: If  $\overline{RD} = 1$ , data outputs remain high impedance. It is recommended that  $\overline{RD}$  will not change during a conversion in order to reduce noise. It is further recommended that  $\overline{RD} = 1$  during conversion to reject any noise present on the data bus.

**Table 1. Logic Truth Table for PXS = 1 (Parallel Mode)**

The MP3276 is easily interfaced to a wide variety of microprocessors and other digital systems. Discussion of the timing requirements of the MP3276 control signals follows.

Figure 1. shows a complete timing diagram for the MP3276 convert start operation.

Either  $\overline{WR}$  or  $\overline{CS}$  may be used to initiate a conversion. We recommend using  $\overline{WR}$  as used in Figure 1. It is quieter and has less propagation delay than  $\overline{CS}$ . If  $\overline{CS}$  is used to trigger the conversion the specified set-up times will be longer.

A conversion is started by taking  $\overline{WR}$  low, then high again (conversion is enabled on the rising edge of  $\overline{WR}$ ). There are two possible conditions that will affect conversion timing.

1. ADEN = 1. At the falling edge of  $\overline{WR}$ , the input channel is determined by the data present on the address bits. The track and hold begins to settle after which STL returns low, indicating that the multiplexer and the buffer amp have settled to less than 1/2 LSB of final value. If the rising edge of  $\overline{WR}$  returns high prior to STL going low, conversion will begin on the falling edge of STL. If the rising edge of  $\overline{WR}$  is delayed until after STL returns low, the input signal is sampled and the conversion is started at the rising edge of  $\overline{WR}$  giving the user better control of the sampling time.

2. ADEN = 0. At the falling edge of  $\overline{WR}$  the data present at the address is ignored and the channel selected during the previous conversion remains selected. In this case the track and hold settling time is omitted and STL never goes high. At the rising edge of  $\overline{WR}$  the input signal is sampled, and conversion is started.

There are two possible states that the data outputs could be in during a conversion.

1. If  $\overline{RD}$  is held high during a conversion the outputs would remain high impedance throughout the conversion. This is the preferred method of operation as any noise present on the data bus is rejected.
2. If  $\overline{RD}$  and  $\overline{CS}$  are held low during a conversion, the data present will be from the previous conversion until the present conversion is completed when STS returns low. The data from the new conversion will appear on the outputs. The state of  $\overline{RD}$  or  $\overline{CS}$  should not change during a conversion.

Once a conversion is started and the STL or STS line goes high, convert start commands will be ignored until the conversion cycle is completed. The output data buffers cannot be enabled during conversion. In addition, all inputs and outputs which change during conversion can introduce noise, and should be avoided when possible.

ADC Write Timing	Time Interval	25°C	Tmin to Tmax	Limits	Comments/Test Conditions

**Serial Data Output Mode (PXS = 0)**

The MP3276 output data is available in serial form when PXS = 0 prior to the  $\overline{RD}$  high-to-low transition. When PXS = 0, the DB11/SDO pin functions as the serial data output. The DB0/SDC pin functions as the serial clock input and all other data outputs are 3-stated.

The serial data output sequence is MSB (DB11) first to LSB (DB0) last. The MSB (DB11) data bit appears at DB11/SDO when STS goes low. The second most significant bit appears at DB11/SDO on the next DB0/SDC high-to-low transition. The LSB (DB0) is present at DB11/SDO on the 11th SDC high-to-low transition.

The control pin functions (ADEN,  $\overline{CS}$ ,  $\overline{WR}$ , and  $\overline{RD}$ ) are the same as the parallel mode of operation. Further information regarding serial control and timing is shown in Figure 6., Table 4. and Table 5.

For a minimum interconnect serial environment, the channel address state can be generated in at least two ways, using an address counter, or using an address serial to parallel converter.  $\overline{WR}$  can then be used as the counter clock or shift register load signal as well as the A/D converter start convert signal on the rising edge. (Note that the falling edge loads the address present at the address port.)

SDC should be in a high state during the STS high period. SDC can make the first high to low transition after t<sub>21</sub>. In normal use it is assumed that PXS is hardwired low. However, if the mode of operation is changed, PXS must go low prior to  $\overline{RD}$  going low.

Figure 6. Serial Data Mode Timing

Serial Data Output Timing	Time Interval	25°C	Tmin to Tmax	Limits	Comments/Test Conditions

**APPLICATION INFORMATION**

The MP3276 is a complete A/D converter system, with its own built-in reference and clock. It may be used by itself (“stand-alone” operation), or it may be interfaced with a microprocessor which can control both conversion and formatting of output.

Successful application of the MP3276 requires careful attention to four main areas:

- 1) Physical layout.
- 2) Connection/Trimming according to mode of operation.
- 3) Conditioning of input signals.
- 4) Control and Timing considerations.

**Physical Layout**

The 12-bit accuracy of the MP3276 represents a dynamic range of 72dB. Precautions must be taken to avoid any interfering signals, whether conducted or radiated, to assure that this is not degraded.

- Avoid placing the chip and its analog signals near logic traces. In general, using a double sided printed circuit card with a good ground plane on the component side is recommended. Routing analog signals between ground traces will help isolate digital control logic. If these lines cross, do so at right angles. The GND Ref. is the positive terminal of the MUX/Instrumentation amplifier and will provide common mode noise rejection. It should be close to and shielded together with the channel inputs in order to take advantage of this feature.
- Power supplies should be quiet and well regulated. Grounds should be tied together at the package and back to the system ground with a single path. Bypass the supplies at the device with a 0.01 to 0.1µF ceramic cap and a 10-47 µF tantalum type, in parallel.

**“Stand-Alone” Operation**

The MP3276 can be used in “stand-alone” operation, which is useful in systems not requiring full computer bus interface capability. This operation is available for either parallel or serial mode.

For this operation,  $\overline{CS} = 0$ ,  $ADEN = 1$ , and conversion is controlled by  $\overline{WR}$ . The 3-state buffers are enabled when  $\overline{RD}$  goes low. There are two possible conditions that the 3-state buffers could be in during a conversion. If  $\overline{RD}$  goes low prior to  $\overline{WR}$ , the output buffers are enabled and the data from the previous conversion is available at the outputs during  $STL = 1$ . At the end of the present conversion which is initiated at the rising edge of  $\overline{WR}$ ,  $STS$  returns low and the new conversion result is placed on the output data buffers.

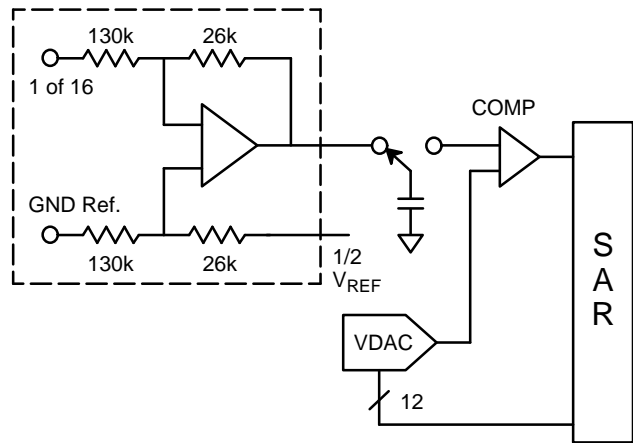

If  $\overline{WR}$  goes low prior to  $\overline{RD}$ , the data buffers remain in a high impedance state and conversion is initiated at the rising edge of  $\overline{WR}$ . Upon the end of the conversion the  $STS$  returns low and the conversion result is placed on the output data buffers. It is

imperative that  $\overline{RD}$  or  $\overline{WR}$  not change during a conversion to insure that errors will not occur.

**Ground Reference**

The ground reference pin can be used for remote ground sensing of a common mode input signal with a maximum 6 V p-p around AGND.

This common input can also be used to dither each input’s “zero”. By averaging multiple conversions digitally, higher resolution for each input conversion can be obtained. Patterns for this dither can be a ramp, a stair step, or white noise.

**Figure 7. Equivalent Input Circuit**

**Quasi Differential Sampling**

*Method 1*

For remote ground sensing where the remote ground does not change more than  $\pm 3$  V from the A/D ground, connect GND Ref to the remote ground.

*Method 2*

Where Method 1 applies to each channel or group of channels, add a mux to allow connecting the appropriate ground to GND Ref.

*Method 3*

Use two parts. Tie both GND Ref pins together and connect this node to the “common” remote GND. Control the sample point by connecting each STL through an “OR” gate whose output is “NAND” connect with  $\overline{WR}$  (inverted  $\overline{WR}$ ). Use this output as  $\overline{WR}$  to both  $\overline{WR}$  inputs. By controlling the  $\overline{WR}$ , sample delay differences between the two converters is minimized. Two parts from the same date code will further minimize this difference. Treat one A/D as the (+) terminal and the other as the (-) terminal of the differential signal. Now the difference can be taken digitally.
